The B horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 6. Chroma of 2 is at depths greater than 20 inches. Texture is fine sandy loam, loam, or silt loam in the fine earth fraction. Structure is weak or moderate, fine to coarse subangular blocky or granular, and consistence is very friable to firm. Reaction ranges from moderately acid to slightly alkaline.

The BC horizon has moderate to weak subangular blocky or platy structure.

The C or Cd horizon has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 1 to 4. Texture is silt loam, loam, very fine sandy loam or fine sandy loam in the fine earth fraction. The horizon is massive and may part to plate-like divisions or has platy structure. Consistence is firm or very firm. Some pedons have a friable C horizon above the Cd. Reaction is slightly alkaline or strongly alkaline.

Ampersand Series

The Ampersand series consists of very deep, somewhat poorly drained soils in depressions on toeslopes and footslopes of glaciated mountains in the Adirondack Upland. Ampersand soils formed in loamy sediments underlain by compact, loamy, very firm lodgment till. Slopes range from 0 to 35 percent (fig. 32).

Ampersand soils are associated on the landscape with Wilmington, Mundalite, Rawsonville, Hogback, and Knob Lock soils. Wilmington soils are poorly drained. Mundalite soils are well drained. Rawsonville soils are moderately deep to meta-igneous bedrock and are well drained. Hogback soils are shallow to meta-igneous bedrock and are well drained. Knob Lock soils are organic, shallow or very shallow to meta-igneous bedrock, and are well to excessively drained.

Typical pedon of Ampersand fine sandy loam, in a map unit of Ampersand-Wilmington complex, 0 to 15 percent slopes, very bouldery, in a wooded area, in the town of Lewis, 200 feet south of a point on Wells Hill Road that is 350 feet east of the upper crossing of Wells Hill Road and Spruce Mill Brook; USGS Ausable Forks 15

Figure 32.—Soil profile of the Ampersand series from a hand dug pit, in the town of Lewis, in a mixed conifer and hardwood forest. The thick, mottled, dark brown subsoil is rich in translocated organic matter and oxides of iron and aluminum.

minute topographic quadrangle; NAD 1983; lat. 44 degrees 16 minutes 53.2 seconds N., long. 73 degrees 39 minutes 42.5 seconds W.

Oe—0 to 1 inch; dark reddish brown (5YR 2/2) moderately decomposed (hemic) plant material; 70 percent fiber unrubbed, 40 percent rubbed; weak fine and medium granular structure; very friable; many fine and very fine, common medium roots; very strongly acid; clear smooth boundary.

Oa1—1 to 3 inches, black (5YR 2/1) highly decomposed (sapric) plant material, 20 percent fiber unrubbed, 5 percent rubbed; weak fine granular structure; very friable; many fine and very fine, and common medium roots; very strongly acid; clear wavy boundary.

Oa2—3 to 4 inches, black (10YR 2/1) highly decomposed (sapric) plant material, 40 percent fine and very fine sand; 10 percent fiber unrubbed, 2 percent rubbed; weak fine granular structure; very friable; many fine and very fine, and common medium roots; strongly acid; abrupt wavy boundary.

E—4 to 5 inches; dark grayish brown (2.5YR 4/2) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and few medium roots; few fine tubular pores; 5 percent rock fragments; very strongly acid; clear broken boundary.

Bhs1—5 to 13 inches; dark reddish brown (5YR 3/3) fine sandy loam; weak medium and coarse subangular blocky structure; friable; common fine and few medium roots; few fine tubular pores; 5 percent rock fragments; strongly acid; gradual wavy boundary.

Bhs2—13 to 19 inches; dark reddish brown (5YR 3/3) fine sandy loam; weak medium and coarse subangular blocky structure; friable; common fine and few medium roots; few fine tubular pores; 5 percent rock fragments; few fine and medium faint dusky red (2.5YR 3/2) soft masses of iron accumulation, and common fine and

medium prominent gray (10YR 5/1) depletions; strongly acid; clear wavy boundary. (Combined thickness of the Bhs horizons is 4 to 16 inches thick)

BC—19 to 24 inches; olive brown (2.5Y 4/3) sandy loam; weak medium and coarse subangular blocky structure; firm; few fine roots; few fine tubular pores; 8 percent rock fragments; few medium and coarse prominent strong brown (7.5YR 5/8), and many fine and medium prominent dark reddish brown (5YR 3/3) soft masses of iron accumulation, and common fine and medium distinct grayish brown (10YR 5/2) depletions; strongly acid; clear wavy boundary. (0 to 16 inches thick)

Cd1—24 to 32 inches; brown (10YR 4/3) gravelly loamy sand; massive with thick plate-like divisions; very firm and brittle; common fine tubular pores; 20 percent rock fragments; common medium distinct strong brown (7.5YR 4/6) soft masses of iron accumulation and few fine distinct grayish brown (10YR /2) iron depletions; strongly acid; clear wavy boundary.

Cd2—32 to 72 inches; interbedded 40 percent grayish brown (2.5Y 5/2) inherited, gravelly sandy loam and olive brown (2.5Y 4/3) gravelly loamy sand; massive with thick plate-like divisions; very firm and brittle; few fine tubular pores in loamy part, and common fine in sandy part; 20 percent rock fragments; common fine and medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation in loamy part; moderately acid.

The thickness of the solum ranges from 20 to 40 inches. Depth to bedrock is greater than 60 inches. Redoximorphic features consisting of Fe depletions or concentrations occur in the Spodic horizon within 20 inches of the mineral soil surface. At least 4 inches of the Bhs and/or the Bh horizons contain 6 percent or more organic carbon by weight. Rock fragments, mainly stones, cobbles, and gravel, range from 5 to 35 percent, by volume, throughout the soil.

The O horizon ranges from fibric material to sapric material. The horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 4, and chroma of 0 to 6. Reaction ranges from extremely acid to strongly acid.

Some pedons have an A horizon that is neutral or has hue of 5YR to 10YR, value of 2 or 3, and chroma of 0 to 2. Texture is fine sandy loam, sandy loam, very fine sandy loam, or loam in the fine-earth fraction. Reaction ranges from extremely acid to strongly acid.

The E horizon has hue of 5YR to 10YR, value of 5 to 7, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, coarse sandy loam, or loamy fine sand in the fine-earth fraction. Reaction ranges from extremely acid to strongly acid.

The Bh horizon, where present, is neutral or has hue of 2.5YR to 7.5YR, value of 2 or 3, and chroma of 0 to 2. Texture is fine sandy loam, sandy loam, coarse sandy loam or loam, in the fine-earth fraction. Consistence is friable or very friable, but up to 25 percent firm areas (ortstein) may be present. Reaction ranges from extremely acid to strongly acid.

The Bhs horizon has hue of 2.5YR to 7.5YR, and value of 3 or less, and chroma of 4 or less. Texture, consistence, and reaction are similar to the Bh horizon.

The Bs horizon has hue of 2.5YR to 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is fine sandy loam, sandy loam, or coarse sandy loam in the fine-earth fraction. Some pedons may have thin sub-horizons of loamy fine sand or loamy sand. Consistence is friable or very friable. Reaction ranges from extremely acid to strongly acid.

A BC horizon is present in some pedons. The horizon has hue of 7.5YR to 2.5Y, value of 3 to 6, and chroma of 1 to 4. Texture is fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand, or loamy sand in the fine-earth fraction. Consistence is friable or firm. Reaction is very strongly acid to moderately acid.

The Cdg or Cd horizon has hue of 7.5YR to 2.5Y, value of 4 or 5, and chroma of 1 to 4. Texture is loamy sand, loamy fine sand, coarse sandy loam, sandy loam, or fine sandy loam. It is massive with or without plate-like divisions, and consistence is firm or very firm. Reaction is very strongly acid through moderately acid.

Andic Cryaquods

Andic Cryaquods soils consist of very deep, somewhat poorly drained soils in depressions on toeslopes and footslopes of glaciated mountains in the Adirondack High Peaks Area. These soils formed in loamy materials underlain by compact, loamy, very firm lodgment till. Slopes range from 3 to 35 percent.

Andic Cryaquods soils are associated on the landscape with Couchsachraga, Esther, Ricker, Santanoni, Skylight, and Wallface soils. Couchsachraga soils are sandy, 4 to 10 inches deep to meta-igneous bedrock, and are somewhat excessively drained and excessively drained. Esther soils are moderately well drained. Santanoni soils are sandy and gravelly, 20 to 40 inches deep to meta-igneous bedrock and are somewhat excessively drained to excessively drained. Wallface soils are 20 to 40 inches deep to meta-igneous bedrock and are well drained. Skylight soils are sandy, 10 to 20 inches deep to meta-igneous bedrock, and are somewhat excessively drained to excessively drained. Ricker soils are organic, 1 to 20 inches deep to meta-igneous bedrock, and are well drained to excessively drained.

Typical pedon of Andic Cryaquods, in a map unit of Andic Cryaquods-Esther complex, 3 to 15 percent slopes, very bouldery, in a wooded area, in the town of Keene, along Skylight Brook, 2 miles upstream from its junction with the South Branch Opalescent River; USGS Mount Marcy 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 04 minutes 51 seconds N. and long. 73 degrees 56 minutes 42 seconds W.

Oe—0 to 7 inches, reddish black (10R 2.5/1) moderately decomposed (hemic) plant material; weak fine granular structure; very friable; many fine and common medium and few coarse roots; extremely acid; gradual wavy boundary.

Oa—7 to 11 inches, reddish black (10R 2.5/1) highly decomposed (sapric) plant material; weak fine granular structure; very friable; many fine and common medium roots; extremely acid; clear wavy boundary.

Bhs1—11 to 13 inches; 70 percent dusky red (2.5YR 3/2) and 30 percent dark reddish brown (2.5YR 3/4) sandy loam; weak medium subangular blocky structure; friable; common fine and few medium roots; 12 percent gravels; very strongly acid; clear wavy boundary.

Bhs2—13 to 24 inches; brown (7.5YR 4/4) sandy loam; weak medium subangular blocky structure; friable; few fine and medium roots; 12 percent gravels; few fine faint strong brown (7.5YR 4/6) redox concentrations as diffuse iron masses in lower part; very strongly acid; gradual wavy boundary.

Bhs3—24 to 36 inches; dark reddish brown (5YR 3/2) sandy loam; weak medium subangular blocky structure; friable; few fine and medium roots; 10 percent gravels and 2 percent stones; few fine faint dark reddish brown (5YR 3/4) redox concentrations, common medium distinct reddish gray (5YR 5/2) redox depletions, and few fine distinct black (5YR 2.5/1) Mn stains; strongly acid; clear wavy boundary.

Cd—36 to 42 inches; olive brown (2.5Y 4/4) gravelly loamy sand; massive; firm, brittle; 25 percent gravels and 5 percent stones; strongly acid.

The thickness of the solum ranges from 20 to 39 inches from the mineral surface. Rock fragment content ranges from 5 to 35 percent in the solum, and 5 to 50 percent in substratum. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil and substratum.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. It is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) plant material. It has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The A horizon (where present), has hue of 7.5YR to 2.5Y, value of 2 or 3, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or coarse sandy loam in the fine-earth fraction. This horizon has weak or moderate, fine or medium granular structure. Consistence is very friable or friable.

The E horizon (where present), has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand or loamy sand in the fine-earth fraction. This horizon has weak fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The Bhs horizons and Bh horizons (where present), have hue of 10R to 7.5YR, with a value and chroma of 3 or less. The Bhs and Bh horizons are fine sandy loam, sandy loam, coarse sandy loam, and can range to loam in some pedons. Ortstein is present in less than 50 percent of some horizons. These horizons have weak or moderate, fine, medium, or coarse granular or subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm.

The Bs horizon has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. This horizon has weak or moderate, fine, medium, or coarse subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm.

The BCd or BC horizon (where present), has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. This horizon is massive with or without medium or thick plate like divisions, or it has weak or moderate, medium or coarse subangular blocky structure. Consistence is friable to very firm and brittle.

The Cd horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is loamy sand, sand, loamy coarse sand, coarse sand, or coarse sandy loam in the fine earth fraction. It is massive with medium or thick plate like divisions. Consistence is firm or very firm and brittle.

Becket Series

The Becket series consists of very deep, well drained soils on summits, shoulders, backslopes, and footslopes of glaciated mountains, hills, ridges, and till plains in the Adirondack Upland. Becket soils formed in loamy sediments underlain by compact, sandy or loamy, very firm lodgment till. Slopes range from 3 to 60 percent (fig. 33).

Becket soils are associated on the landscape with Skerry, Adirondack, Tunbridge, Lyman, Tahawus, and Monadnock soils. Skerry soils are moderately well drained. Adirondack soils are somewhat poorly drained. Tunbridge soils are moderately deep to meta-igneous bedrock. Lyman soils are shallow to meta-igneous bedrock. Tahawus soils are very poorly drained and are sandy. Monadnock soils are loamy over sandy or gravelly.

Typical pedon of Becket fine sandy loam, 8 to 15 percent slopes, in a wooded area, in the town of North Hudson, 1.5 miles north of the junction of Elk Lake Road and Blue Ridge Road, in a road cut along the east side of road; USGS Schroon Lake 15 minute topographic quadrangle; NAD 1927; lat. 43 degrees 58 minutes 26 seconds N. and long. 73 degrees 49 minutes 56 seconds W.

Oe—0 to 2 inches, very dark gray (5YR 3/1) moderately decomposed (hemic) plant material; weak fine and medium granular structure; friable; many fine and very fine roots; very strongly acid; abrupt smooth boundary.

E—2 to 3 inches, gray (5YR 6/1) fine sandy loam; weak fine and medium granular structure; friable; many fine and very fine, few medium roots; 10 percent rock fragments; very strongly acid; abrupt smooth boundary.

Bhs—3 to 5 inches, dark reddish brown (5YR 3/2) fine sandy loam; common medium distinct dark reddish brown (2.5YR 2.5/4) ortstein nodules; weak fine and medium

Figure 33.—Soil profile of the Becket series from a road cut, in the town of North Hudson, in a northern hardwoods forest. The gray substratum is a very firm, dense, acidic till derived mostly from anorthositic gneiss. Iron and aluminum oxides with some organic matter form the reddish brown "spodic horizon" subsoil.

subangular blocky structure; friable; many fine and very fine, few medium roots; 10 percent rock fragments; very strongly acid; clear smooth boundary.

Bs—5 to 9 inches, reddish brown (5YR 4/4) sandy loam; weak fine and medium subangular blocky structure; friable; common fine and very fine, few medium roots; 10 percent rock fragments; very strongly acid; clear wavy boundary.

BC1—9 to 18 inches, dark yellowish brown (10YR 4/6) sandy loam; weak medium subangular blocky structure; friable; common fine and very fine, few medium roots; 14 percent rock fragments; very strongly acid; clear smooth boundary.

BC2—18 to 33 inches, dark yellowish brown (10YR 4/4) sandy loam; weak medium subangular blocky structure; friable; common fine and very fine, few medium roots; 14 percent rock fragments; strongly acid; abrupt wavy boundary.

Cd1—33 to 47 inches, light olive brown (2.5Y 5/4) gravelly loamy sand; massive with medium plate like divisions; very firm, brittle; 30 percent rock fragments; many medium and coarse distinct dark reddish brown (2.5YR 2.5/4) soft masses of iron accumulation on plate surfaces; strongly acid; clear smooth boundary.

Cd2—47 to 72 inches, light gray (10YR 7/2) gravelly loamy sand; massive with medium plate like divisions; very firm, brittle; 30 percent rock fragments; strongly acid.

Mineral solum thickness ranges from 20 to 36 inches. Reaction ranges from extremely acid to slightly acid in the solum, and from very strongly acid to neutral in the substratum. Rock fragment are dominantly gravel and range from 5 to 30 percent in the solum and from 5 to 40 percent in the substratum. Rock fragments constitute less than 35 percent of the particle-size control section. Ortstein ranges from 0 to 20 percent of the spodic horizon.

The O horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 4, and chroma of 0 to 4. It is slightly, moderately or highly decomposed plant material.

Some pedons have an A horizon that has hue of 5YR to 10YR, value of 2 to 4, and chroma of 1 to 3. It is up to 6 inches thick.

Disturbed areas have an Ap horizon with hue of 7.5YR or 10YR, value of 3 or 4, and chroma of 2 to 4.

The A and Ap horizons are dominantly fine sandy loam, but include loam and sandy loam in the fine-earth fraction. Structure is granular.

The E horizon has hue of 5YR to 2.5Y, value of 4 to 7, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or loamy sand in the fine-earth fraction. Structure is granular or subangular blocky or the horizon is massive.

The Bhs horizon has hue of 2.5YR to 7.5YR, value of 2 to 3, and chroma of 1 to 3. Texture is dominantly fine sandy loam, but includes loam and sandy loam in the fine-earth fraction. Structure is granular or subangular blocky or the horizon is massive.

Some pedons have a Bh horizon has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 1 to 4. Texture range is the same as the Bhs horizon.

The Bs horizon has hue of 2.5YR to 10YR, value of 3 to 8 and chroma of 2 to 8. Texture is fine sandy loam or sandy loam in the fine-earth fraction. Structure is granular or subangular blocky or the horizon is massive.

The BC horizon has hue of 10YR to 5Y, value and chroma of 3 to 6. Texture is fine sandy loam, sandy loam, loamy fine sand, or loamy sand in the fine-earth fraction. Structure is granular, platy, or subangular blocky or the horizon is massive.

The Cd horizon has hue of 10YR to 5Y, value of 4 to 7, and chroma of 2 to 6. It is comprised of loamy layers and sandy pockets and lenses with horizontal orientation, with a composite texture of loamy sand, loamy fine sand, sandy loam, fine sandy loam, or their gravelly analogues. The lenses are coarse, medium, or fine sand and are 1/8 to 3 inches thick. They make up 20 percent or more of the horizon. They are massive with or without plate-like divisions. Consistence is firm or very firm. Some pedons have friable C horizons up to 8 inches thick.

Bombay Series

The Bombay series consists of very deep, moderately well drained soils on summits, shoulders, and backslopes of glaciated ridges, and on till plains in the Champlain Valley. Bombay soils formed in loamy sediments underlain by firm, loamy, calcareous lodgment till. Slopes range from 3 to 8 percent.

Bombay soils are associated on the landscape with Nellis, Amenia, Howard, Cayuga, Vergennes, and Kingsbury soils. Nellis soils are well drained and have lower clay content in the solum. Amenia soils have lower clay content in the solum. Howard soils are gravelly and are well drained to excessively drained. Cayuga soils are clayey over loamy. Vergennes soils are clayey. Kingsbury soils are clayey and somewhat poorly drained.

Typical pedon of Bombay gravelly loam, in a hay field, in the town of Willsboro, 200 feet east of a point on Point Road that is 900 feet south of the junction of Point Road and Indian Bay Road; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 25 minutes 34 seconds N. and long. 73 degrees 22 minutes 28 seconds W.

Ap—0 to 10 inches, dark brown (10YR 3/3) gravelly loam; pale brown 10YR 6/3 dry; weak medium and fine granular structure; very friable; many very fine, and common fine and medium roots; common fine tubular pores; 20 percent gravel and 5 percent cobbles; slightly acid; abrupt smooth boundary.

Bt/E—10 to 18 inches, dark yellowish brown (10YR 4/4) gravelly loam; weak medium and thick platy parting to weak medium and fine subangular blocky structure; friable; many very fine and few fine roots; common fine tubular and few medium vesicular pores; few thin clay films on surfaces along pores; brown (10YR 5/3) ped exteriors 1 to 2 mm thick that constitutes less than 15 percent E material in the layer; 15 percent gravel and 5 percent cobbles; few fine distinct yellowish brown

(10YR 5/6) soft masses of iron accumulation in lower part; slightly acid; clear wavy boundary.

Bt—18 to 25 inches, dark yellowish brown (10YR 4/4) gravelly loam; weak medium subangular blocky structure; friable; common very fine roots; common very fine and fine tubular and vesicular pores; common distinct moderately thick clay films on surfaces along pores and on all faces of peds; 20 percent gravel; common fine and medium distinct yellowish brown (10YR 5/6) and few fine faint brown (10YR 5/3) soft masses of iron accumulation; slightly acid; clear smooth boundary.

BC—25 to 36 inches, [dark] brown (10YR 4/3) gravelly loam; weak thick platy parting to weak fine subangular blocky structure; friable; common very fine roots; few very fine tubular pores; 20 percent gravel; few secondary calcium carbonate accumulations along surfaces of rock fragments and between plates; common fine distinct yellowish brown (10YR 5/6) and few fine faint brown (10YR 5/3) soft masses of iron accumulation; slightly alkaline, slightly effervescent; clear wavy boundary.

C—36 to 72 inches, light olive brown (2.5Y 5/4) gravelly fine sandy loam; massive with plate-like divisions; firm; few very fine roots; 15 percent gravel and 5 percent cobbles; one 5 mm thick layer of secondary calcium carbonate in upper part; few fine distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; moderately alkaline, strongly effervescent.

The thickness of the solum ranges from 30 to 60 inches. Depth to bedrock is greater than 60 inches. Depth to carbonates is 25 to 70 inches. Redoximorphic features occur within 40 inches of the mineral soil surface. Rock fragments range from 5 to 30 percent, by volume, in the mineral solum and from 10 to 35 percent in the substratum.

The Ap horizon has hue of 7.5YR to 2.5Y, value of 3 or 4 and chroma of 2 or 3. Texture is silt loam, loam or fine sandy loam in the fine earth fraction. This horizon has weak or moderate, fine or medium granular structure, and very friable or friable consistence. Reaction ranges from strongly acid to slightly acid.

The BE horizon, where present, has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 6. Texture is silt loam, loam, very fine sandy loam, or fine sandy loam in the fine earth fraction. The horizon is massive, or it has weak or moderate granular, subangular blocky, or platy structure. Consistence is very friable to firm. Reaction ranges from strongly acid to neutral.

Some pedons have an E horizon with higher value that replaces the BE horizon.

The Bt/E horizons have properties like the Bt horizon in the interiors of the peds, and E-like material on the exterior of ped. The E material has hue of 7.5YR to 2.5Y, value of 5 to 8 and chroma of 2 to 6. Redoximorphic accumulations may or may not be present in the Bt/E horizons. Reaction ranges from strongly acid to neutral.

The Bt horizon has hue of 5YR to 10YR, value of 3 to 5 and chroma of 3 to 6. Texture is silt loam, loam, or fine sandy loam in the fine earth fraction. Structure is weak or moderate, subangular blocky. Consistence is friable or firm. Redoximorphic accumulations range from few to many. Reaction ranges from strongly acid to neutral.

The BC horizon has texture and color similar to the Bt horizon except for value which is generally higher. Structure is subangular blocky or platy, or the horizon is massive. Redoximorphic accumulations range from few to many. Reaction ranges from moderately acid to slightly alkaline.

The C or Cd horizon has hue of 5YR to 2.5Y, value of 3 to 6 and chroma of 2 to 4. Texture is fine sandy loam or loam in the fine earth fraction. The horizon is massive or may have weak or moderate plate-like divisions. Consistence is friable or firm. Redoximorphic accumulations range from few to many. Reaction ranges from slightly acid to moderately alkaline.

Bucksport Series

The Bucksport series consists of very deep, very poorly drained soils in depressions on ground moraines, outwash plains, lake plains, and glacial till plains. Bucksport soils formed in organic deposits greater than 51 inches thick. Slopes range from 0 to 1 percent.

Bucksport soils are associated on the landscape with Wonsqueak, Typic Endoaquolls, Pyrities, Sunapee, Kalurah, and Malone soils. Wonsqueak soils have a 16 to 51 inch thick organic deposit. Typic Endoaquolls soils are loamy, and have a less than 16 inch organic deposit. Kalurah soils are loamy and moderately well drained. Malone soils are loamy and somewhat poorly drained. Pyrities soils are loamy and are well drained.

Typical pedon of Bucksport mucky peat, in the town of Clinton, Clinton County NY, about 2.3 miles west of intersection of Clinton MIlls Road and Bull Run Road, and 50 feet south of Clinton Mills Road; USGS Ellenburg Depot 7.5 minute topographic quadrangle; NAD 1927; lat. 44 degrees 57 minutes 34 seconds N. and long. 73 degrees 52 minutes 17 seconds W.

Oe—0 to 7 inches; dark reddish brown (5YR 2/2) mucky peat; 50 percent unrubbed fiber, 35 percent rubbed fiber; weak medium and fine granular structure; nonsticky, nonplastic; common medium, fine, and very fine roots; strongly acid (5.2 in 0.01M calcium chloride); clear smooth boundary.

Oa1—7 to 31 inches; dark reddish brown (5YR 3/2) muck; 40 percent unrubbed fiber and 10 percent rubbed fiber; weak medium and fine subangular blocky structure; nonsticky, nonplastic; few fine and very fine roots; very strongly acid (5.0 in 0.01M calcium chloride); clear smooth boundary.

Oa2—31 to 47 inches; black (5YR 2/1) muck; 30 percent unrubbed fiber and 5 percent rubbed fiber; weak medium subangluar blocky structure; nonsticky, nonplastic; extremely acid (4.1 in 0.01M calcium chloride); gradual smooth boundary.

Oa3—47 to 72 inches; black (5YR 2/1) muck; 10 percent unrubbed fiber and 5 percent rubbed fiber; massive; nonsticky, nonplastic; very strongly acid (4.8 in 0.01M calcium chloride).

The thickness of the organic material is greater than 51 inches and ranges to over 12 feet. The depth to bedrock is more than 60 inches. The content of woody fragments ranges from 0 to 20 percent throughout the soil and consists of twigs, branches, and stumps. The content of mineral material ranges from 0 to 20 percent throughout. Fibers are typically of herbaceous and woody origin but in some pedons fibers from sphagnum moss make up 70 percent of the surface tier and make up thin layers in the subsurface and bottom tier.

The surface tier is neutral or has hue of 2.5YR to 10YR, value of 2 to 4 and chroma of 0 to 2. The surface tier is typically sapric material but in some pedons is hemic or fibric material with or without sapric materials. This tier is massive or has weak fine or medium granular, weak fine or medium subangular or weak thin platy structure. Consistence is nonsticky or slightly sticky. Reaction ranges from extremely acid to strongly acid in 0.01M calcium chloride.

The subsurface and bottom tiers have hue of 2.5YR to 10YR, value of 2 to 4 and chroma of 1 to 3. These tiers are typically sapric material but some pedons have thin layers of fibric material with a total thickness of less than 5 inches or thin layers of hemic material with a total thickness of less than 10 inches. The tiers are massive or have weak thin to very thick platy or weak fine or medium subangular blocky structure. Consistence is nonsticky or slightly sticky. Reaction ranges from extremely acid to moderately acid in the subsurface tier and very strongly acid to slightly acid in the bottom tier in 0.01M calcium chloride.

Burnt Vly Series

The Burnt Vly series consists of very deep, very poorly drained mucky soils on broad flood plains, in depressions on outwash plains and deltas, and on toeslopes and upland depressions of glaciated hills and ridges in the Adirondack Upland. Burnt Vly soils formed in saturated, decomposing plant material overlying sandy sediments. Slopes range from 0 to 1 percent.

Burnt Vly soils are associated on the landscape with Pleasant Lake, Rumney, Colton, Searsport, Naumburg, Tahawus, Adirondack, and Monadnock soils. Pleasant Lake soils are greater than 51 inches deep to mineral soil. Rumney soils are loamy and poorly drained. Colton soils are gravelly and excessively drained. Searsport and Tahawus soils are sandy. Naumburg soils are sandy and somewhat poorly drained. Adirondack soils are loamy and somewhat poorly drained. Monadnock soils are loamy over sandy and are well drained.

Typical pedon of Burnt Vly peat, in the town of St Armand, 300 feet south of River Road, and .5 miles from Route 3 junction at Bloomingdale; USGS Saranac Lake 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 24 minutes 07 seconds N. and long. 74 degrees 04 minutes 38 seconds W.

Oi—0 to 10 inches, light yellowish brown 2.5Y 6/4) broken face and rubbed peat (fibric material); 95 percent unrubbed fiber, 90 percent rubbed fiber; massive; very friable; many very fine, few medium and coarse roots; extremely acid; abrupt smooth boundary.

Oe—10 to 15 inches, black (10YR 2/1) broken face and very dark gray (10YR 3/1) rubbed mucky peat (hemic material); 75 percent unrubbed fiber, 30 percent rubbed fiber; weak fine subangular blocky structure; very friable; common very fine roots; extremely acid; clear smooth boundary.

Oa1—15 to 24 inches, black (10YR 2/1) broken face and very dark brown (10YR 2/2) rubbed muck (sapric material); 12 percent unrubbed fiber, less than 1 percent rubbed fiber; weak fine and medium subangular blocky structure; very friable; common very fine roots; extremely acid; clear smooth boundary.

Oa2—24 to 34 inches, very dark brown (10YR 2/2) broken face and rubbed muck (sapric material); 12 percent unrubbed fiber, less than 1 percent rubbed fiber; weak medium subangular blocky structure; very friable; very strongly acid; abrupt smooth boundary.

2Cg1—34 to 56 inches, grayish brown (2.5Y 5/2) loamy fine sand; massive; friable; moderately acid; abrupt smooth boundary.

2Cg2—56 to 72 inches, olive gray (5Y 5/2) very fine sandy loam; massive; friable; moderately acid.

The depth to the mineral horizon ranges from 16 to 51 inches. In some pedons, the mineral layer is a single layer 12 inches or more thick with organic material above and below. The organic part of the control section has a pH of less than 4.5 in 0.01M calcium chloride.

The surface tier has hue of 2.5Y to 10YR, or is neutral, value of 2 to 7, and chroma of 0 to 6. Values normally increase several units when pressed. Fiber content ranges from 75 to 95 percent before rubbing and 30 to 90 after rubbing.

In some pedons the surface tier is muck or mucky peat.

The subsurface tier has hue of 10YR to 5YR, or is neutral, value of 2 to 6, and chroma of 0 to 3. The materials are dominantly muck (sapric material), but layers of peat (fibric material) totaling less than 5 inches in thickness and mucky peat (hemic material) totaling less than 10 inches are in some pedons. This horizon typically is massive with some pedons having a weak platy, blocky, or granular structure.

The 2C horizon has hue of 2.5YR to 5Y, value of 3 to 6, and chroma of 0 to 6. Texture is sand, loamy sand, fine sand, very fine sand, loamy fine sand, gravelly loamy

sand, gravelly sand, or very gravelly sand. Reaction ranges from extremely acid to slightly acid. Some pedons have thin strata of very fine and/or fine sandy loam.

Catden Series

The Catden series consists of very deep, very poorly drained soils in shallow bays of Lake Champlain, and in depressions on deltas and lake plains in the Champlain Valley. Catden soils formed in deep, saturated, decomposing plant material. Slopes range from 0 to 2 percent.

Catden soils are associated on the landscape with Whallonsburg, Vergennes, Kingsbury, Covington, Windsor, and Howard soils. Whallonsburg soils are 16 to 51 inches deep to clay. Vergennes, Kingsbury, and Covington soils are clayey and are moderately well drained, somewhat poorly drained, and poorly drained respectively. Windsor soils are sandy and excessively drained. Howard soils are gravelly and are well drained to excessively drained.

Typical pedon of Catden muck, in the town of Chesterfield, 800 feet south of the Clinton County line and 140 feet west of Lake Champlain (40 feet west of road), in Wickham Marsh; USGS Keeseville 7.5 minute quadrangle; NAD 1927; lat. 44 degrees 32 minutes 21 seconds N. and long. 73 degrees 25 minutes 07 seconds W.

Oa1—0 to 3 inches, black (10YR 2/1) muck; 30 percent unrubbed fiber, 5 percent rubbed fiber; weak fine granular structure; very friable; common fine roots; 5 percent woody fragments; 10 percent fine and very fine sand; neutral; abrupt smooth boundary.

Oa2—3 to 6 inches, very dark gray (10YR 3/1) muck; 20 percent unrubbed fiber, 3 percent rubbed fiber; weak fine granular structure; very friable; common fine roots; 5 percent woody fragments; 50 percent fine and very fine sand; neutral; abrupt smooth boundary.

Oa3—6 to 37 inches, black (5YR 2.5/1) muck; 35 percent unrubbed fiber, 5 percent rubbed fiber; massive; very friable; few fine roots in upper part; 15 percent woody fragments; 5 percent very fine sand; slightly acid; gradual smooth boundary.

Oa4—37 to 46 inches, dark reddish brown (5YR 2.5/2) muck; 40 percent unrubbed fiber, 10 percent rubbed fiber; massive; very friable; 15 percent woody fragments; 5 percent very fine sand; slightly acid; gradual smooth boundary.

Oa5—46 to 71 inches, dark reddish brown (5YR 2.5/2) muck; 65 percent unrubbed fiber, 15 percent rubbed fiber; massive; very friable; 20 percent woody fragments; 5 percent very fine sand; neutral; gradual smooth boundary.

Oa6—71 to 80 inches, dark reddish brown (5YR 3/2) muck; 30 percent unrubbed fiber, 5 percent rubbed fiber; massive; very friable; 10 percent woody fragments; 5 percent very fine sand; neutral.

The organic material extends to a depth of 51 inches or more. The reaction throughout the pedon ranges from very strongly acid to neutral in 0.01M calcium chloride. The pH value is 4.5 or more (in 0.01M calcium chloride) in one or more layers of organic soil materials within the control section. Woody fragments occur throughout the profile in most pedons consisting of twigs, branches, logs or stumps, and range from 0 to 30 percent by volume in the control section. Fragments range in size from 3/4 inch to more than a foot in diameter.

The surface tier has hue of 5YR to 2.5Y, or is neutral; value of 1 to 4, and chroma of 0 to 6. This tier is dominantly muck (sapric material); however, some pedons have surface layers of peat (fibric material) or mucky peat (hemic material). The structure of the surface tier is weak or medium, coarse to fine granular or subangular blocky, or is massive.

The subsurface tier has hue of 5YR to 2.5Y, or is neutral, value of 2 to 3, and chroma of 0 to 4. Chroma or value or both may change from 0.5 to 2 units upon

rubbing. Broken faces become darker upon brief exposure to air. The layer is dominated by sapric material with a rubbed fiber content of less than 17 percent of the organic volume. The subsurface tier has granular or blocky structure or is massive. The unrubbed, well-decomposed organic material resembles woody plant tissue.

The bottom tier has colors similar to the subsurface tier and has variable amounts of woody and herbaceous layers, however, woody fibers are dominant. This tier commonly is massive but in some pedons it has weak coarse blocky or thick platy structure. The subsurface and bottom tiers are dominantly sapric material but some pedons have thin layers of hemic material.

Cayuga Series

The Cayuga series consists of very deep, moderately well drained soils on backslopes and footslopes of ridges and on lake plains in the Champlain Valley. Cayuga soils formed in clayey lake-laid sediments underlain by dense, calcareous lodgment till. Slopes range from 3 to 15 percent.

Cayuga soils are associated on the landscape with Churchville, Vergennes, Kingsbury, Nellis, Amenia, and Bombay soils. Churchville soils are somewhat poorly drained. Vergennes soils are clayey throughout. Kingsbury soils are clayey throughout and somewhat poorly drained. Nellis soils are loamy and well drained. Amenia and Bombay soils are loamy throughout.

Typical pedon of Cayuga silty clay loam, 3 to 8 percent slopes, in the town of Essex, 80 feet west of a point on Middle Road that is 1,700 feet south of the junction of Middle Road and School Road, in a hay field; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 17 minutes 39 seconds N. and long. 73 degrees 22 minutes 42 seconds W.

Ap—0 to 8 inches, dark brown (10YR 3/3) silty clay loam; pale brown (10YR 6/3) dry; moderate medium granular structure; friable; many fine and very fine roots; 1 percent rock fragments; slightly acid; abrupt smooth boundary.

E—8 to 14 inches, brown (10YR 5/3) silty clay loam; moderate medium subangular blocky structure; firm; common fine and very fine roots; 5 percent rock fragments; many medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation; moderately acid; clear smooth boundary.

Bt1—14 to 19 inches, brown (10YR 4/3) clay; moderate medium subangular blocky structure; firm; common fine and very fine roots; common medium faint grayish brown (10YR 5/2) silt coatings, light gray (10YR 7/2) dry, on ped exteriors 2 millimeters thick; many moderately thick clay films on ped faces and pore linings; 5 percent rock fragments; common medium prominent strong brown (7.5YR 5/8) soft masses of iron accumulation in lower part; neutral; clear smooth boundary.

Bt2—19 to 24 inches, brown (10YR 4/3) clay; strong fine and medium angular blocky structure; firm; few fine and very fine roots; continuous thick clay films on ped faces and pore linings; 10 percent rock fragments; common medium faint yellowish brown (10YR 5/4) soft masses of iron accumulation; neutral; clear smooth boundary.

BC—24 to 28 inches, very dark grayish brown (10YR 3/2) clay loam; massive parting to moderate medium angular blocky structure; firm; few fine and very fine roots; 10 percent rock fragments; common medium faint grayish brown (10YR 5/2) iron depletions and common medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; moderately alkaline, strongly effervescent; clear smooth boundary.

2C—28 to 72 inches, very dark grayish brown (10YR 3/2) silt loam; massive; firm; 15 percent rock fragments; moderately alkaline, violently effervescent.

The thickness of the solum ranges from 20 to 40 inches. Depth to bedrock is greater than 60 inches. Depth to the lithologic till substratum is 20 to 40 inches. Rock fragments range from 0 to 10 percent by volume above the lithologic discontinuity and from 10 to 50 percent below. Depth to carbonates ranges from 20 inches to 60 inches or more.

The Ap horizon has hue of 7.5YR to 2.5Y, value of 3 or 4 and chroma of 2 to 4. Texture of the fine-earth fraction ranges from fine sandy loam to silty clay loam. Reaction ranges from moderately acid to neutral.

The E horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 2 or 3. Texture of the fine-earth fraction ranges from fine sandy loam through silty clay loam. Structure is weak or moderate, subangular blocky or platy, or the horizon is massive. Consistence is friable or firm. Reaction ranges from moderately acid to neutral.

In some pedons a Bt/E horizon replaces or underlies the E horizon. The E part has moist colors similar to the E horizon and dry color value of 6 to 8 and chroma of 2 or 3.

The Bt horizon has hue of 5YR to 2.5Y, value of 3 to 5, and chroma of 3 or 4. In pedons lacking Bt/E horizons, the upper 2 to 4 inches of the Bt horizon has uncoated silt and sand grains on faces of peds 1 to 2 millimeters thick with dry color with value of 6 to 8 and chroma of 2 or 3. The horizon often lacks redoximorphic features, but some pedons have few or common, faint or distinct iron oxide concentrations. Texture of the fine-earth fraction ranges from silty clay loam or clay loam, through clay. Structure is moderate or strong, fine to coarse, subangular or angular blocky, or prismatic over structure parting to these. Consistence is firm or very firm. Reaction ranges from moderately acid to slightly alkaline.

Some pedons have a BC horizon with hue of 5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 4. Texture is silty clay loam or clay loam to clay. Structure is moderate or strong, medium or coarse subangular or angular blocky, or it is massive. Consistence is firm or very firm. Reaction ranges from slightly acid to moderately alkaline.

The 2C horizon has hue of 5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 4. Texture of the fine-earth fraction is fine sandy loam, loam, clay loam, silt loam or silty clay loam. Reaction ranges from neutral to moderately alkaline. Free carbonates are present in most pedons.

Champlain Series

The Champlain series consists of very deep, excessively drained to somewhat excessively drained, sandy soils on deltas, outwash plains, outwash terraces, and high stream terraces in the Adirondack Upland. Champlain soils formed in stratified, water deposited sandy sediments. Slopes range from 3 to 45 percent.

Champlain soils are associated on the landscape with Mooers, Colton, Monadnock, Becket, Tunbridge, Rumney, and Burnt Vly soils. Mooers soils are moderately well drained. Colton soils are gravelly and excessively drained. Monadnock soils are loamy over sandy or gravelly, and are well drained. Becket soils are loamy and well drained. Tunbridge soils are loamy, well drained, and moderately deep to meta-igneous bedrock. Rumney soils are loamy and poorly drained. Burnt Vly soils are mucky and very poorly drained.

Typical pedon of Champlain loamy sand, 3 to 8 percent slopes, in a hay field, 50 feet east of a point on Cheney Road that is 1.4 miles south of the junction of Cheney Road and Pelfershire Road; USGS Port Henry 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 03 minutes 44 seconds N. and long. 73 degrees 29 minutes 02 seconds W.

Ap1—0 to 7 inches; very dark grayish brown (10YR 3/2) loamy sand; weak fine granular structure; very friable; many fine and few medium roots; 7 percent rock fragments; moderately acid; clear wavy boundary.

Ap2—7 to 10 inches; brown (10YR 4/3) loamy sand; weak medium subangular blocky parting to weak medium granular structure; very friable; many fine roots; 5 percent rock fragments; moderately acid; abrupt smooth boundary.

Bw1—10 to 16 inches; strong brown (7.5YR 4/6) sand; weak fine and medium subangular blocky structure; very friable; common fine roots; 5 percent rock fragments; few fine tubular pores; slightly acid; abrupt wavy boundary.

Bw2—16 to 24 inches; yellowish brown (10YR 5/4) fine sand; single grain; loose; common fine roots; 3 percent rock fragments; slightly acid; clear wavy boundary.

BC—24 to 35 inches; light olive brown (2.5Y 5/4) fine sand; single grain; loose; few fine roots; less than 1 percent rock fragments; slightly acid; gradual wavy boundary.

C1—35 to 50 inches; grayish brown (2.5Y 5/2) fine sand; single grain; loose; few fine roots; slightly acid; clear smooth boundary.

C2—50 to 72 inches; pale brown (10YR 6/3) and dark grayish brown (10YR 4/2) sand; single grain; loose; few fine roots; 1 percent rock fragments; slightly acid.

The thickness of the solum ranges from 12 to 36 inches. Depth to bedrock is greater than 60 inches. Rock fragments, mainly gravel, range from 0 to 10 percent, by volume, throughout the soil.

Some pedons have an O horizon composed of fibric or hemic material. Reaction ranges from extremely acid to strongly acid.

The Ap horizon has a hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is fine sand, loamy fine sand, sand or loamy sand in the fine earth fraction. This horizon has fine or medium granular and subangular blocky structure. Consistence is very friable or friable. Reaction ranges from strongly acid to slightly acid.

Some pedons have an A horizon in place of the Ap horizon.

The Bw horizon has hue of 7.5YR or 10YR, value of 4 to 6, and chroma of 3 to 8. Texture is dominantly fine sand but ranges to loamy fine sand, sand or loamy sand in the fine earth fraction. This horizon has subangular blocky structure or is single grain. Consistence is very friable or loose. Reaction ranges from strongly acid to slightly acid.

The BC horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 6. Texture is dominantly fine sand, but ranges to loamy fine sand, sand or loamy sand in the fine earth fraction. Consistence is single grain and loose or very friable. Reaction is moderately acid to neutral.

The C horizon has hue of 10YR to 5Y, value of 4 to 7, and chroma of 1 to 6. Texture is fine sand, loamy fine sand, sand or loamy sand in the fine earth fraction. Reaction ranges from moderately acid to neutral.

Charles Series

The Charles series consists of very deep, poorly drained soils on flood plains in intermontane valleys of the Adirondack Upland. Charles soils formed in silty sediments deposited by flood waters. Slopes range from 0 to 2 percent.

Charles soils are associated on the landscape with Lovewell, Cornish, Medomak, Depeyster, Monadnock and Skerry soils. Lovewell soils are moderately well drained. Cornish soils are somewhat poorly drained. Medomak soils are very poorly drained. Depeyster soils are higher in clay and moderately well drained. Monadnock soils are loamy over sandy or gravelly, and are well drained. Skerry soils are loamy and moderately well drained.

Typical pedon of Charles silt loam, in the town of Keene, on the west side of Marcy Airfield, 500 feet north of a light pole in the parking area, at the margin of brush and field; USGS Mount Marcy 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 13 minutes 09 seconds N. and long. 73 degrees 47 minutes 22 seconds W.

Ap—0 to 9 inches, very dark grayish brown (10YR 3/2) silt loam; light brownish gray (10YR 6/2) dry; moderate fine granular structure; very friable; common fine and

very fine, few medium roots; common fine distinct dark brown (7.5YR 3/4) oxidized rhizospheres; strongly acid; abrupt smooth boundary.

A—9 to 16 inches, very dark gray (2.5Y 3/1) silt loam; gray (2.5Y 6/1) dry; moderate medium granular structure; very friable; few fine and very fine roots; few fine and very fine tubular, and few fine vesicular pores; common fine and medium distinct dark yellowish brown (10YR 3/4) and few fine prominent dark reddish brown (5YR 3/4) oxidized rhizospheres; strongly acid; clear smooth boundary.

Cg1—16 to 28 inches, dark gray (2.5Y 4/1) silt loam; massive; very friable; few fine and very fine tubular pores; less than 1 percent rock fragments; common medium faint grayish brown (2.5Y 5/2) iron depletions, and common fine distinct dark yellowish brown (10YR 3/4) soft masses of iron accumulation; strongly acid; gradual wavy boundary.

Cg2—28 to 38 inches, grayish brown (2.5Y 5/2) silt loam; massive; very friable; few fine and very fine tubular pores; common medium distinct light olive brown (2.5Y 5/4) and common fine prominent dark brown (7.5YR 3/4) soft masses of iron accumulation; strongly acid; clear wavy boundary.

Cg3—38 to 46 inches, light brownish gray (2.5Y 6/2) very fine sandy loam; massive; very friable; few fine and very fine tubular pores; common fine prominent yellowish brown (10YR 5/6) soft masses of iron accumulation on pore linings; moderately acid; clear wavy boundary.

2Cg4—46 to 52 inches, dark gray (5Y 4/1) loamy fine sand; single grain; loose; moderately acid; gradual wavy boundary.

2Cg5—52 to 72 inches, dark gray (5Y 4/1) loamy sand; single grain; loose; 14 percent rock fragments; moderately acid.

Depth to bedrock is more than 60 inches. A few fine pebbles occur in some pedons. Reaction ranges from extremely acid to slightly acid throughout, unless limed, but some sub-horizon within the control section has a reaction of moderately acid or slightly acid. Some pedons have buried horizons.

The Ap horizon has hue of 10YR to 5Y, value of 3 or 4 and chroma of 1 to 3. Dry value is 6 or 7. Undisturbed areas have an A horizon 1 to 5 inches thick, that has hue of 10YR to 5Y, value of 3 or 4 and chroma of 1 to 3. They are silt loam or very fine sandy loam. They have weak or moderate, fine or medium granular structure.

The C horizon has hue of 2.5Y to 5BG, value of 4 to 6, and chroma of 1 to 3. At least one sub-horizon between a depth of 10 and 30 inches has a hue of 2.5Y, value of 4 or 5, and chroma of 2. It is silt loam, very fine sandy loam, or loamy very fine sand, and in some pedons below 40 inches, there are strata of silt loam to fine gravel with gravel ranging from 0 to 15 percent. The upper part of the C horizon has weak, fine or medium granular structure or it is massive. The lower part of the C horizon is massive or single grain. Consistence ranges from loose to friable.

Correlation Note: In the CkA map unit has an A horizon that is thicker than the range of the Charles series. This should not significantly affect use and management on a local basis for most purposes.

Charlton Series

The Charlton series consists of very deep, well drained soils on summits, shoulders, backslopes, and footslopes of hills and ridges, and on till plains in the Champlain Valley. Charlton soils formed in loamy, friable sediments deposited by glacial ice. Slopes range from 3 to 35 percent.

Charlton soils are associated on the landscape with Chatfield, Hollis, Georgia, Vergennes, Kingsbury, and Windsor soils. Chatfield and Hollis soils are moderately deep and shallow respectively to meta-igneous bedrock. Georgia soils are moderately well drained. Vergennes and Kingsbury soils are clayey and moderately well drained

and somewhat poorly drained respectively. Windsor soils are sandy and excessively drained.

Typical pedon of Charlton gravelly fine sandy loam, in a map unit of Charlton-Chatfield complex, 8 to 15 percent slopes, rocky, very stony, in a woodlot, in the town of Westport, 1,050 feet due north of a point on County Route 8, that is 150 feet east of the junction of County Route 8 and Eggleston Road; USGS Port Henry 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 14 minutes 02 seconds N. and long. 73 degrees 28 minutes 12 seconds W.

A—0 to 5 inches, very dark grayish brown (10YR 3/2) gravelly fine sandy loam; moderate fine and medium granular structure; very friable; many fine and medium, and common coarse roots; 20 percent rock fragments; moderately acid; clear smooth boundary.

Bw1—5 to 11 inches, strong brown (7.5YR 4/6) gravelly sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and medium, and few coarse roots; 20 percent rock fragments; moderately acid; clear wavy boundary.

Bw2—11 to 19 inches, dark yellowish brown (10YR 4/4) gravelly sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and medium, and few coarse roots; 20 percent rock fragments; moderately acid; clear wavy boundary.

BC—19 to 36 inches, yellowish brown (10YR 5/4) gravelly fine sandy loam; weak thin and medium platy structure; friable; few fine and medium roots; 15 percent rock fragments; moderately acid; clear wavy boundary.

C1—36 to 45 inches, dark yellowish brown (10YR 4/4) gravelly sandy loam; massive with weak thin and medium plate-like divisions; firm; 15 percent rock fragments; moderately acid; clear wavy boundary.

C2—45 to 72 inches, 60% light yellowish brown (2.5Y 6/4) and 40 percent brown (10YR 4/3) fine sandy loam; massive with weak medium and thick plate-like divisions; firm; 10 percent rock fragments; common fine and medium distinct strong brown (7.5YR 5/8) soft masses of iron accumulation on plate surfaces; moderately acid.

The thickness of the solum ranges from 20 to 38 inches. Depth to bedrock is commonly more than 6 feet. Rock fragments range from 5 to 35 percent by volume to a depth of 40 inches and up to 50 percent below 40 inches. Except where the surface layer is stony, the fragments are mostly subrounded gravel and typically make up 60 percent or more of the total rock fragments. Unless the soil is limed, reaction ranges from very strongly acid to moderately acid.

The A horizon has hue of 7.5YR or 10YR, value of 2 or 3, and chroma of 1 to 3. Disturbed pedons have an Ap horizon with value of 3 or 4 and chroma of 2 to 4. The A or Ap horizon is sandy loam, fine sandy loam, or loam in the fine-earth fraction. This horizon has weak or moderate granular structure and is friable or very friable.

Some pedons have a thin E horizon below the A horizon. It has hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 1 to 3. Texture, structure, and consistence are like the A horizon.

The upper part of the Bw horizon has hue of 7.5YR or 10YR and value and chroma of 4 to 6. The lower part of the Bw horizon has hue of 10YR or 2.5Y and value and chroma of 4 to 6. Texture of the Bw horizon is loam, fine sandy loam, or sandy loam with less than 65 percent silt plus very fine sand in the fine earth fraction. It has weak granular or subangular blocky structure, or it is massive. Consistence is friable or very friable.

Some pedons have a BC horizon with value and chroma like the lower part of the Bw horizon, but includes hue of 5Y. The BC horizon commonly has texture, structure, and consistence like the Bw horizon but the range includes non-pedogenetically derived structure appearing in the form of thin plates.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 2 to 6. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction, with pockets or thin lenses of loamy sand. The horizon is massive or is non-pedogenetically derived, appearing in the form of thin plates. Consistence commonly is very friable or friable but in some pedons includes firm.

Chatfield Series

The Chatfield series consists of moderately deep, well drained soils on summits, shoulders, and backslopes of hills and ridges in the Champlain Valley. Chatfield soils formed in loamy sediments deposited by glacial ice, and are underlain by massive meta-igneous bedrock. Slopes range from 3 to 60 percent (fig. 34).

Chatfield soils are associated on the landscape with Pittsfield, Charlton, Hollis, Vergennes, Kingsbury, and Windsor soils. Pittsfield and Charlton soils are very deep to bedrock. Hollis soils are shallow to meta-igneous bedrock. Vergennes and Kingsbury soils are very deep, clayey, and are moderately well drained and somewhat poorly drained respectively. Windsor soils are very deep, sandy and excessively drained.

Typical pedon of Chatfield gravelly fine sandy loam, 8 to 15 percent slopes, from a map unit of Chatfield-Hollis Complex, 8 to 15 percent slopes, very rocky, very stony, in the town of Chesterfield, .95 miles south on Mace Chasm Road from the intersection with Port Douglass Road, and .17 mile east of Mace Chasm Road. Follow trail across Mud Brook, take extreme left fork, 50 feet off trail to east, 10 feet north of rock outcrop, in a forested area. USGS Willsboro 15 minute quadrangle; 44 degrees 28 minutes 50 seconds north latitude and 73 degrees 27 seconds 36 minutes west longitude; NAD 1927.

Oe—0 to 1 inch, moderately decomposed plant material.

A—1 to 7 inches, dark brown (10YR 3/3) gravelly fine sandy loam; pale brown (10YR 6/3) dry); weak fine granular structure; very friable; common medium roots; 15 percent rock fragments; strongly acid; abrupt smooth boundary.

Bw1—7 to 19 inches, strong brown (7.5YR 4/6) gravelly fine sandy loam; weak medium subangular blocky structure; very friable; common medium roots; 34 percent rock fragments; moderately acid; abrupt smooth boundary.

Bw2—19 to 27 inches, strong brown (7.5YR 4/6) fine sandy loam; moderate fine subangular blocky structure; very friable; common medium roots; 10 percent rock fragments; moderately acid; clear smooth boundary.

C—27 to 32 inches, brown (7.5YR 4/4) fine sandy loam; massive; friable; 10 percent rock fragments; moderately acid; abrupt smooth boundary.

R—32 inches, meta-igneous bedrock.

The thickness of the solum ranges from 16 to 36 inches. Depth to bedrock ranges from 20 to 40 inches. Rock fragments range from 5 to 50 percent by volume in the A horizon and from 5 to 35 percent in the B and C horizons. Rock fragments are typically gravel or channers but include cobbles and flagstones, particularly just above the bedrock.

The O horizon has hue of 7.5YR to 2.5Y, value of 2 or 3, and chroma of 0 to 2. It is slightly to highly decomposed organic material. Structure is granular or subangular blocky, or is massive. Consistence is very friable. Reaction ranges from extremely acid to moderately acid.

The A or Ap horizon has hue of 7.5YR to 2.5Y, value of 2 to 4, and chroma of 1 to 4. Dry value is 6 or higher. Texture ranges from sandy loam to loam in the fine-earth fraction. Structure is weak or moderate, fine or medium granular. Consistence is friable or very friable. Reaction ranges from very strongly acid to moderately acid, unless limed.

The AB or BA horizon has hue of 7.5YR to 2.5Y, value of 3 or 4, and chroma of 2 to 4. Texture is similar to the A horizon.

Figure 34.—Soil profile of the Chatfield series from a road cut, in the town of Westport, in a mixed pine and hardwood forest. Note the very stony surface. Depth to anorthositic gneiss bedrock (left of the spade) is about 30 inches.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 3 to 6, and chroma of 4 to 6. Texture ranges from sandy loam to silt loam in the fine-earth fraction. The Bw horizon has fine to coarse, subangular blocky or granular structure, and is friable or very friable. Reaction ranges from very strongly acid to moderately acid. Some pedons have a BC horizon with color and texture similar to the C horizon.

The C horizon, where present, has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 2 to 4. It ranges from sandy loam to silt loam in the fine-earth fraction and may have lenses or pockets of loamy sand. It is massive and may have plate-like divisions. It is friable or firm. Reaction ranges from very strongly to moderately acid.

The R horizon is dominantly schist, granite, or gneiss bedrock. In places, it is massive, but it dominantly has vertical and horizontal fractures in the upper 12 to 30 inches, but lacks significant displacement below the upper few inches.

Churchville Series

The Churchville series consists of very deep, somewhat poorly drained soils on footslopes of ridges and on lake plains in the Champlain Valley. Churchville soils formed in clayey lake-laid sediments underlain by dense, calcareous lodgment till. Slopes range from 2 to 8 percent.

Churchville soils are associated on the landscape with Cayuga, Kingsbury, Pittsfield, Nellis, Amenia, Chatfield, and Hollis soils. Cayuga soils are moderately well drained. Kingsbury soils are clayey throughout. Pittsfield and Nellis soils are loamy and well drained. Amenia soils are loamy and moderately well drained. Chatfield and Hollis soils are well drained, and are moderately deep and shallow to meta-igneous bedrock respectively (fig. 35).

Typical pedon of Churchville loam, 2 to 8 percent slopes, in a headland of a corn field, in the town of Essex, 830 feet north of a point on State Route 22 that is located 1,300 feet west of the intersection of State Route 22 and Middle Road; USGS Willsboro 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees 18 minutes 32 seconds N. and long. 73 degrees 23 minutes 09 seconds W.

Ap—0 to 9 inches, dark brown (10YR 3/3) loam; pale brown (10YR 6/3) dry; weak medium and coarse subangular blocky structure parting to weak fine granular structure; friable; common fine and few medium and coarse roots; 5 percent rock fragments; neutral; abrupt smooth boundary.

Bt1—9 to 13 inches, brown (10YR 4/3) clay; light brownish gray (2.5Y 6/2) ped faces; weak medium and coarse subangular blocky structure; friable; few fine and medium roots; common fine vesicular and few fine and medium tubular pores; common thin clay films on ped faces and few thin discontinuous clay films in pore linings; many fine faint brown (7.5YR 4/4) and few fine distinct strong brown (7.5YR 4/6) soft masses of iron accumulation; neutral; clear wavy boundary.

Bt2—13 to 25 inches, brown (10YR 4/3) clay; light brownish gray (10YR 6/2) ped faces; weak coarse prismatic parting to moderate fine and medium subangular blocky structure; firm; few fine roots; few very fine vesicular and tubular pores; common thin clay films on ped faces; 3 percent rock fragments; common medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation; neutral; clear smooth boundary.

2Cd1—25 to 35 inches, 60 percent brown (10YR 5/3) and 40 percent olive brown (2.5Y 4/4) gravelly fine sandy loam; massive with medium and thick plate like

Figure 35.—Soil profile of the Churchville series from a backhoe test pit, in the town of Essex, in a hay field. The contact between the blue-gray, clayey subsoil (Bt horizon) and the gray-brown, loamy substratum (2C horizons) is well expressed in this photo.

divisions; firm; few fine roots; few fine vesicular and tubular pores; 19 percent rock fragments; common distinct yellow (10YR 7/8) carbonate coats on plate surfaces; common fine and medium faint yellowish brown (10YR 5/4) soft masses of iron accumulation; slightly alkaline, slightly effervescent; clear wavy boundary.

2Cd2—35 to 48 inches, grayish brown (2.5Y 5/2) gravelly fine sandy loam; massive with medium and thick plate like divisions; firm; few fine vesicular and tubular pores; 17 percent rock fragments; strongly alkaline, violently effervescent; gradual wavy boundary.

2Cd3—48 to 72 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive; very firm; few fine vesicular and tubular pores; 13 percent rock fragments; strongly alkaline, violently effervescent.

The thickness of the solum and depth to the 2C horizon ranges from 20 to 40 inches. Depth to carbonates ranges from 20 to 50 inches. Depth to bedrock is greater than 60 inches. Volume of rock fragments, mostly gravel and channers, range from 0 to 10 percent in the solum and from 10 to 35 percent in the 2C horizon. Dominant chroma of more than 2 occurs in some subhorizons between the Ap and 30 inches.

The Ap horizon has hue of 2.5Y to 5YR, moist value of 3 to 5 and dry value of 6 or 7, with chroma of 2 or 3. Texture ranges from fine sandy loam to silty clay loam. Reaction ranges from moderately acid to neutral.

The E horizon, where present, has hue of 2.5Y to 2.5YR, value of 4 to 6 and chroma of 2 to 4, with common or many redoximorphic features. Texture ranges from fine sandy loam to silty clay loam. Structure is weak or moderate blocky or platy, consistence is friable or firm and reaction ranges from moderately acid to slightly alkaline.

The B/E horizon, where present, has ped coats similar in color and texture to the E horizon. Total thickness of the skeletons between adjoining peds is less than 5 mm and less than 15 percent of the soil volume. Ped interiors (B portion) have color value of 4 or 5 and chroma from 2 to 4. Structure is weak or moderate blocky or platy, consistence is friable or firm and reaction ranges from moderately acid to slightly alkaline. In some pedons the E or B/E horizon is replaced by an E/B or BE horizon.

The Bt horizon has hue of 2.5Y to 2.5YR, value of 3 to 5 and chroma of 2 to 4, with common or many redoximorphic features. Ped coatings have chroma of 2 or less. Texture is clay loam, silty clay loam, silty clay, or clay with a range in clay content from 35 to 55 percent. Structure is weak to strong, angular or subangular blocky, or prismatic. Clay films range from patchy to continuous on both horizontal and vertical ped faces. Reaction ranges from slightly acid to slightly alkaline.

Some pedons have a BC horizon with hue of 2.5Y to 2.5YR, value of 3 to 5 and chroma of 1 to 4, with common or many redoximorphic features.

The 2C 0r 2Cd horizon has hue of 2.5Y to 2.5YR, value of 3 to 5, and chroma of 1 to 4. Redoximorphic features range from none to common. Texture of the fine earth fraction is very fine sandy loam, fine sandy loam, loam, silt loam or silty clay loam. Consistence is friable to very firm. Reaction is slightly alkaline or strongly alkaline.

Claverack Series

The Claverack series consists of very deep, moderately well drained soils on deltas and beach ridges in the Champlain Valley. Claverack soils formed in sandy sediments underlain by clayey lacustrine or marine sediments. Slopes range from 0 to 8 percent.

Claverack soils are associated on the landscape with Cosad, Kingsbury, Cayuga, Deerfield, Howard, Amenia, and Farmington soils. Cosad soils are somewhat poorly drained. Kingsbury soils are clayey throughout and are somewhat poorly drained. Cayuga soils are clayey over loamy. Deerfield soils are sandy throughout. Howard soils are gravelly and are well to excessively drained. Amenia soils are loamy. Farmington soils are loamy, shallow to limestone bedrock, and well drained (fig. 36).

Typical pedon of Claverack loamy fine sand, 0 to 3 percent slopes, in the town of Essex, 300 feet south of a point on State Route 22 that is located 3,250 feet west of the hamlet of Essex, in an abandoned hay field; USGS Willsboro 15 minute quadrangle; NAD 1927; lat. 44 degrees 18 minutes 27 seconds N. and long. 73 degrees 22 minutes 04 seconds W.

Ap—0 to 12 inches, dark brown (10YR 3/3) loamy fine sand; pale brown (10YR 6/3) dry; weak fine and medium granular structure; very friable; many fine and very fine roots; moderately acid; abrupt smooth boundary.

Bw1—12 to 16 inches, dark yellowish brown (10YR 4/4) fine sand; weak medium subangular blocky structure; very friable; few fine and very fine roots; moderately acid; clear smooth boundary.

Bw2—16 to 22 inches, brown (10YR 4/3) fine sand; weak medium subangular blocky structure; friable; few medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation and few fine faint grayish brown (10YR 5/2) iron depletions at 20 inches; slightly acid; clear smooth boundary.

BC—22 to 26 inches, brown (10YR 4/3) fine sand; massive; firm; common medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation; neutral; abrupt smooth boundary.

2C—26 to 72 inches, dark grayish brown (10YR 4/2) clay; massive; firm; common medium prominent strong brown (7.5YR 5/6) soft masses of iron accumulation; slightly alkaline, slightly effervescent.

The thickness of the solum and depth to the underlying fine-textured material ranges from 20 to 40 inches. Depth to bedrock is greater than 60 inches. The soil contains few or no rock fragments. Soil reaction ranges from strongly acid to neutral in the solum and from neutral to moderately alkaline in the substratum.

The A or Ap horizon has hue of 7.5YR or 10YR, value of 3 or 4, 6 to 8 dry, and chroma of 2 or 3. Texture is fine sandy loam, loamy fine sand, loamy sand or sand. Structure is weak, very fine to medium, granular.

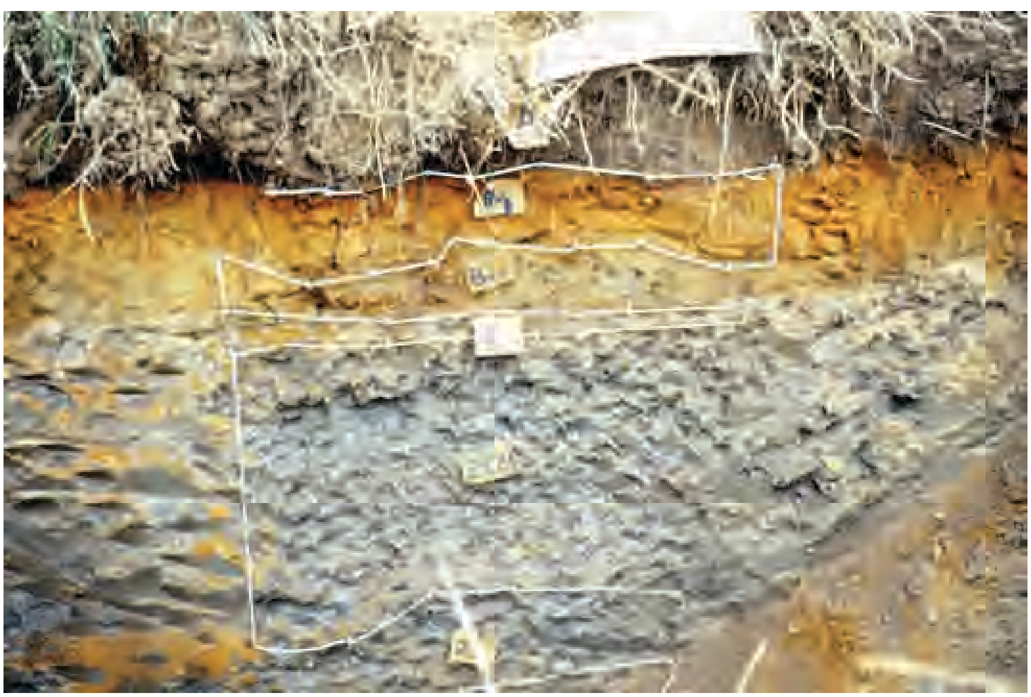

Figure 36.—Soil profile of the Claverack series from a backhoe test pit, in the town of Essex, in a hay field. The contact between the reddish brown, sandy subsoil (Bw horizons) and the gray clayey substratum (2C horizons) is well expressed in this photo.

The B horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 6 and few to common high chroma mottles. In places the lower part of the B horizon has gray or grayish brown mottles below a depth of 18 inches. Texture ranges from loamy fine sand to sand. Small areas of uncoated sand grains have colors with chroma of 2 and value of 6 or 7. This horizon is structureless or has weak, very fine through medium, subangular blocky structure.

The 2C horizon has hue of 2.5YR to 5Y, value of 3 to 6, and chroma of 2 to 6. Texture ranges from silty clay loam to clay. Some pedons have subhorizons up to 5 inches thick that are silt or silt loam. The horizon is massive or has weak or moderate, medium or thick plate-like divisions as depositional varves. Free carbonates are usually present.

Collamer Series

The Collamer series consists of very deep, moderately well drained soils on lacustrine terraces and lake plains in the Champlain Valley. Collamer soils formed in silty clay sediments deposited in still water. Slopes range from 2 to 8 percent.

Collamer soils are associated on the landscape with Dunkirk, Niagara, Claverack, Pittsfield, Chatfield, and Hollis soils. Dunkirk soils are well drained. Niagara soils are somewhat poorly drained. Claverack soils are sandy over clayey. Pittsfield soils are loamy and are well drained. Chatfield and Hollis soils are loamy, well drained, and moderately deep and shallow to meta-igneous bedrock respectively.

Typical pedon of Collamer silt loam, 2 to 8 percent slopes, in a hay field, in the town of Crown Point, 65 feet east of a point on Sugar Hill Road that is 2,100 feet south of the junction of Sugar Hill Road and Routes 9N and 22; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 56 minutes 40 seconds N. and long. 73 degrees 25 minutes 54 seconds W.

Ap—0 to 11 inches, dark grayish brown (10YR 4/2) silt loam; moderate fine and medium granular structure; friable; many fine and few medium roots; neutral; abrupt smooth boundary.

B/E—11 to 16 inches, 87 percent dark brown (10YR 3/3) (B part) and 13 percent pale brown (10YR 6/3) (E part) silty clay loam; moderate fine and medium subangular blocky structure; friable; common fine roots; common fine and medium tubular pores; nearly continuous thin clay films in pore linings; few fine distinct dark yellowish brown (10YR 4/4) and few fine faint brown (10YR 4/3) soft masses of iron accumulation; neutral; gradual wavy boundary.

Bt—16 to 25 inches, dark brown (10YR 3/3) silty clay loam; moderate fine and medium subangular blocky structure; friable; few fine roots; common fine and few medium and coarse tubular pores; nearly continuous thick clay films on ped faces and pore linings; common fine faint dark yellowish brown (10YR 4/4) soft masses of iron accumulation and common medium faint dark grayish brown (10YR 4/2) and grayish brown (10YR 5/2) iron depletions; neutral; clear wavy boundary.

C1—25 to 35 inches, grayish brown (10YR 5/2) silt loam; weak thin and medium platy structure; friable; 1 percent rock fragments; common fine and medium distinct dark yellowish brown (10YR 4/4) and light olive brown (2.5Y 5/4) soft masses of iron accumulation and few medium distinct very pale brown (10YR 7/3) soft masses of secondary calcium carbonate accumulation; moderately alkaline, strongly effervescent; gradual wavy boundary.

C2—35 to 72 inches, brown (10YR 4/3 & 5/3) silt loam; weak thin and medium platy; firm; 2 percent rock fragments; common fine and medium faint dark yellowish brown (10YR 4/4) soft masses of iron accumulation, and few fine distinct gray (10YR 6/1) iron depletions; moderately alkaline, strongly effervescent.

The thickness of solum ranges from 24 to 52 inches. Bedrock is deeper than 60 inches. Depth to carbonates ranges from 20 to 72 inches. Rock fragments range from

0 to 5 percent throughout; however, in some pedons that are underlain with till, rock fragment content ranges up to 35 percent by volume below a depth of 40 inches. Reaction ranges from strongly acid to neutral in surface layer and upper part of the subsoil, moderately acid to slightly alkaline in the lower part of the subsoil, and is slightly acid to moderately alkaline in the substratum.

The Ap or A horizon has hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 2 or 3. Texture of the fine-earth fraction is fine sandy loam, very fine sandy loam, or silt loam. It has weak or moderate granular or subangular blocky structure. Consistence is very friable or friable.

In some pedons, an E horizon is present. This horizon has hue of 5YR to 2.5Y, value of 5 or 6, and chroma of 2 to 4. It normally has common or many high chroma redoximorphic features. Texture of the fine-earth fraction ranges from fine sandy loam to silt loam. This horizon is massive, or has weak platy or subangular blocky structure. Consistence ranges from very friable to firm.

The E/B and B/E horizons have E horizon-like material on exteriors of peds and are like the Bt horizon in interior of peds. The B/E horizon has few to many redoximorphic concentrations with chroma of 3 or more.

The Bt horizon has hue of 5YR to 2.5Y, value of 4 or 5, chroma of 3 to 6, above 30 inches and chroma of 2 to 6 below 30 inches. It has few to many, low chroma redoximorphic depletions and high chroma redoximorphic concentrations. Texture of the fine-earth fraction is silt loam or silty clay loam except individual thin subhorizons range from fine sandy loam to silty clay. It has weak to moderate subangular blocky, angular blocky, or prismatic structure.

A BC horizon is present in some pedons. The horizon has hue of 5YR to 2.5Y. It has weak or moderate platy or prismatic structure.

The C horizon has hue of 5YR to 2.5Y, value of 4 or 5, and chroma of 2 to 4. Texture of the fine-earth fraction is silty clay loam to stratified silt and very fine sand.

Some pedons, below a depth of 40 inches, have a 2C horizon with textures of gravelly loam through channery silty clay loam.

Correlation Note: In the CrB map unit has a B horizon that has a color value darker than typical for the range of the Collamer series. This should not significantly affect use and management on a local basis for most purposes.

Colonie Series

The Colonie series consists of very deep, somewhat excessively drained soils on deltas, kame terraces, and beach ridges in the Champlain Valley. Colonie soils formed in stratified, water deposited, sandy sediments, overlying coarser, calcareous sands with some fine gravels. Slopes range from 3 to 25 percent.

Colonie, calcareous substratum soils are associated on the landscape with Factoryville, Dunkirk, Collamer, Hartland, and Howard soils. Factoryville soils lack the calcareous sands in the substratum. Dunkirk and Collamer soils are silty clay, and are well drained and moderately well drained respectively. Hartland soils are silty and well drained.

Typical pedon of Colonie, calcareous substratum, loamy fine sand, in a map unit of Factoryville-Colonie complex, 3 to 8 percent slopes, in an idle hay field, in the town of Crown Point, 70 feet east of a point on Pearl Street that is 6,400 feet southwest of the junction of Pearl Street and County Route 2; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 56 minutes 21 seconds N. and long. 73 degrees 27 minutes 27 seconds W.

Ap—0 to 9 inches, dark brown (10YR 3/3) loamy fine sand; pale brown (10YR 6/3) dry; weak fine granular structure; very friable; many fine and very fine, and few medium roots; 3 percent rock fragments; moderately acid; abrupt smooth boundary.

E1—9 to 14 inches, dark yellowish brown (10YR 4/6) loamy fine sand; weak medium subangular blocky structure; very friable; common fine and very fine, few medium roots; 3 percent rock fragments; moderately acid; clear smooth boundary.

E2—14 to 25 inches, yellowish brown (10YR 5/6) fine sand; weak medium and coarse subangular blocky structure; very friable; common very fine and few fine and medium roots; 3 percent rock fragments; moderately acid; clear wavy boundary.

E and Bt1—25 to 37 inches, yellowish brown (10YR 5/4) fine sand; weak medium and coarse subangular blocky structure; very friable; few very fine and fine roots; very few very thin dark yellowish brown (10YR 4/6) clay films or bridges between sand grains; 2 percent rock fragments; slightly acid; clear wavy boundary.

E and Bt2—37 to 49 inches, light olive brown (2.5Y 5/4) fine sand; weak medium subanglar blocky structure; very friable; few very fine and fine roots; few thin dark yellowish brown (10YR 4/6) clay bridging of sand grains; neutral; abrupt irregular boundary.

2C1—49 to 56 inches, grayish brown (2.5Y 5/2) fine sand; single grain; loose; contains 1/2 to 1 inch strata that are dark yellowish brown (10YR 4/6) fine sand; few very fine roots; moderately alkaline, strongly effervescent; abrupt wavy boundary.

2C2—56 to 61 inches, light olive brown (2.5Y 5/4) fine sand; massive; friable; few very fine roots; neutral; abrupt wavy boundary.

2C3—61 to 72 inches, grayish brown (2.5Y 5/2) fine sand; single grain; loose; contains 1/2 to 1 inch strata that are dark yellowish brown (10YR 4/6) fine sand; few very fine roots; moderately alkaline, strongly effervescent.

The thickness of the solum ranges from 40 to more than 80 inches. The depth to the first lamellae ranges from 14 to 48 inches. Typically, rock fragments are lacking, but some pedons contain up to 5 percent fine gravel throughout the soil. Reaction is very strongly acid to neutral in the solum, and strongly acid to moderately alkaline in the C horizon. Some pedons have carbonates below 40 inches.

The Ap or A horizon has hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 2 or 4, moist. Dry colors have value of 5 to 7 and chroma of 2 or 3. Texture is fine sand to very fine sandy loam. Structure is weak granular, or it is single grain. Consistence is very friable or loose.

The E horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 3 to 8 in the upper part and 2 to 8 in the lower part. Texture is dominantly fine sand or loamy fine sand with some pedons containing thin very fine sand subhorizons. It is massive or single grain, or has weak granular or subangular blocky structure. Consistence is very friable or loose.

Some pedons have a Bw horizon.

The (E and Bt) horizon has properties similar to the E horizon and contains horizontal lamellae (Bt) that have hue of 5YR to 10YR, value of 3 to 5, and chroma of 3 to 6, and are typically darker colored than the soil in the interlamellar areas. The lamellae are fine sand to fine sandy loam and are friable to firm. In some pedons, some of the lamellae do not have a distinct increase in clay content.

Some pedons may have a BC horizon.

The C horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 6. Some pedons have redoximorphic features below 40 inches. Texture is dominantly fine sand or loamy fine sand; however, some pedons have contrasting layers of finer textured deposits, or coarser deposits ranging to fine gravel, below depths of 48 inches.

Colton Series

The Colton series consists of very deep, excessively drained soils on kame terraces, outwash plains, outwash terraces, and high stream terraces in the Adirondack Upland. Colton soils formed in stratified, water deposited, gravelly sediments. Slopes range from 0 to 60 percent.

Colton soils are associated on the landscape with Adams, Monadnock, Rumney, Burnt Vly, Becket, and Tunbridge soils. Adams soils are dominantly sand. Monadnock soils are loamy over sandy or gravelly, and are well drained. Rumney soils are loamy and are poorly drained. Burnt Vly soils are mucky and are very poorly drained. Becket soils are loamy and well drained. Tunbridge soils are loamy, well drained, and moderately deep to meta-igneous bedrock.

Typical pedon of Colton very gravelly loamy sand, in a map unit of Colton-Adams complex, 3 to 15 percent slopes, in a wooded area, in the town of Chesterfield, 250 feet south of Nesbit Pond in Clear Pond Park, on the edge of a gravel pit; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 23 minutes 00 seconds N. and long. 73 degrees 35 minutes 04 seconds W.

Oi—0 to 1 inch; dark yellowish brown (10YR 4/4) slightly decomposed (fibric) plant material; 98 percent unrubbed fiber, 95 percent rubbed fiber; weak medium platy structure; very friable; strongly acid; clear smooth boundary.

Oe—1 to 2 inches; very dark brown (7.5YR 2.5/2) moderately decomposed (hemic) plant material; 80 percent unrubbed fiber, 40 percent rubbed fiber; moderate fine and medium granular; very friable; many fine and medium and common coarse roots; strongly acid; abrupt smooth boundary.

E—2 to 3 inches; grayish brown (10YR 5/2) very gravelly loamy sand; weak fine granular structure; very friable; many fine and medium and common coarse roots; 40 percent gravels, 4 percent cobbles, and 1 percent stones; strongly acid; clear smooth boundary.

Bhs—3 to 6 inches; dark brown (7.5YR 3/3) very gravelly loamy sand; weak fine and medium subangular blocky structure; very friable; many fine and medium and common coarse roots; 40 percent gravels, 4 percent cobbles, and 1 percent stones; strongly acid; clear smooth boundary.

Bs—6 to 13 inches; brown (7.5YR 4/4) very gravelly loamy sand; weak medium subangular blocky structure; very friable; common fine and medium, and few coarse roots ; 40 percent gravels, 4 percent cobbles, and 1 percent stones; strongly acid; clear smooth boundary.

BC—13 to 21 inches; dark yellowish brown (10YR 4/6) very gravelly loamy sand; single grain; loose; common fine and medium and few coarse roots; 40 percent gravels, 4 percent cobbles, and 1 percent stones; moderately acid; clear smooth boundary.

C—21 to 72 inches, dark yellowish brown (10YR 4/4) extremely gravelly coarse sand; single grain; loose; few fine and medium roots; 55 percent gravels, 14 percent cobbles, 1 percent stones; moderately acid.

The thickness of the solum ranges from 18 to 45 inches. Depth to bedrock is greater than 60 inches. Rock fragments, mainly gravel and cobbles, range from 5 to 55 percent in the surface and subsurface layers, from 15 to 55 percent in the subsoil, and from 35 to 70 percent in the C horizon.

Some undisturbed pedons have an O horizon that has hue of 5YR to 10YR or is neutral, value of 2 to 4, and chroma of 0 to 4. It is up to 8 inches thick.

The Ap horizon has hue of 10YR to 5YR, value of 2 to 5, and chroma of 2 to 4. Texture is sand, loamy coarse sand, loamy sand, loamy fine sand, sandy loam or fine sandy loam in the fine-earth fraction. It has granular structure or it is structureless. Reaction is extremely acid to moderately acid unless limed. Some pedons have a thin A horizon with chroma of 0 to 3.

The E horizon has hue of 5YR to 10YR, value of 4 to 7, and chroma of 1 or 2. Texture is coarse sand, sand, loamy coarse sand, loamy sand, loamy fine sand or coarse sandy loam in the fine-earth fraction. Some pedons have thin horizons of fine sandy loam. Reaction is extremely acid to moderately acid.

The Bhs, or Bh, horizon has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 1 to 3. Texture is coarse sand, sand, loamy coarse sand, loamy sand, or loamy fine sand

in the fine-earth fraction. Some pedons have thin horizons of fine sandy loam. It has granular or subangular blocky structure, or it is massive. It is very friable or friable, with or without cemented masses. Reaction is extremely acid to moderately acid.

The Bs horizon has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 3 to 8. Texture is coarse sand, sand, loamy coarse sand, loamy sand, or loamy fine sand in the fine-earth fraction. Some pedons are coarse sandy loam in the upper part. Some pedons have thin horizons of fine sandy loam. It has granular or subangular blocky structure, or it is massive or single grain. Reaction is extremely acid to moderately acid.

The BC horizon has hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 2 to 6. Texture is coarse sand, sand, loamy coarse sand, loamy sand, or loamy fine sand in the fine-earth fraction. Reaction is extremely acid to moderately acid.

Some pedons have a CB horizon with properties similar to the BC.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 7, and chroma of 2 to 6. It is composed of gravel, cobbles, or stones with coarse sand, loamy coarse sand, loamy sand, or sand in the interstices and has varying degrees of stratification. Reaction is very strongly acid to slightly acid.

Cornish Series

The Cornish series consists of very deep, somewhat poorly drained soils on flood plains in intermontane valleys of the Adirondack Upland. Cornish soils formed in silty sediments deposited by flood waters. Slopes range from 0 to 2 percent.

Cornish soils are associated on the landscape with Lovewell, Charles, Adams, Depeyster, Podunk, Monadnock, and Tunbridge soils. Lovewell soils are moderately well drained. Charles soils are poorly drained. Adams soils are sandy and are somewhat excessively drained. Depeyster soils are silty and are moderately well drained. Podunk soils are loamy and are moderately well drained. Monadnock soils are loamy over sandy or gravelly and are well drained. Tunbridge soils are loamy, well drained, and moderately deep to meta-igneous bedrock.

Typical pedon of Cornish silt loam, 0 to 2 percent slopes, in the town of Jay, 75 feet south of Clark Road, and 1/10 mile east of house at the end of the road; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 24 minutes 16 seconds N. and long. 73 degrees 41 minutes 59 seconds W.

Ap—0 to 12 inches, very dark grayish brown (10YR 3/2) silt loam; light brownish gray (10YR 6/2) dry; moderate fine granular structure; very friable; many fine and very fine roots; slightly acid; abrupt smooth boundary.

Bw—12 to 21 inches, brown (10YR 4/3 & 5/3) silt loam; moderate fine and medium subangular blocky structure; friable; common fine and very fine roots; common fine and very fine tubular pores; less than 1 percent rock fragments; common fine distinct yellowish brown (10YR 5/6) soft masses of iron accumulation, and common coarse faint grayish brown (10YR 5/2) iron depletions; moderately acid; gradual wavy boundary.

C1—21 to 35 inches, dark grayish brown (10YR 4/2) silt loam; massive; friable; few fine and very fine roots; few fine and common very fine tubular pores; less than 1 percent rock fragments; common coarse faint brown (10YR 5/3) and common fine and medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; moderately acid; clear wavy boundary.

C2—35 to 42 inches, dark grayish brown (10YR 4/2) very fine sandy loam; massive; friable; few fine and very fine tubular pores; less than 1 percent rock fragments; common medium distinct brown (7.5YR 4/4) and common coarse faint brown (10YR 5/3) soft masses of iron accumulation, and common fine and medium distinct light brownish gray (10YR 6/2) iron depletions; moderately acid; gradual wavy boundary.

C3—42 to 48 inches, dark yellowish brown (10YR 4/4) loamy sand; single grain; loose; 7 percent rock fragments; few medium distinct light brownish gray (10YR 6/2) iron depletions; moderately acid; abrupt wavy boundary.

C4—48 to 53 inches, brown (10YR 5/3) and light brownish gray (10YR 6/2) silt loam; massive; friable; less than 1 percent rock fragments; many medium and coarse distinct yellowish brown (10YR 5/8) soft masses of iron accumulation; slightly acid; gradual wavy boundary.

C5-—3 to 72 inches, brown (10YR 5/3) and light brownish gray (10YR 6/2) loamy fine sand; massive; very friable; less than 1 percent rock fragments; many medium and coarse distinct yellowish brown (10YR 5/6) and common medium distinct reddish brown (5YR 4/4) soft masses of iron accumulation; slightly acid.

The thickness of the solum ranges from 20 to 48 inches. Depth to bedrock is more than 60 inches. A few pebbles are in some pedons. Redox depletions are between depths of 7 to 16 inches. Reaction ranges from very strongly acid to slightly acid throughout, unless limed, but pedons that are stratified may range to neutral below 40 inches. Some pedons have buried horizons.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 to 4. Dry value is 6 or 7. Undisturbed areas have an A horizon 1 to 6 inches thick, that has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 to 4. They are silt loam or very fine sandy loam. They have weak to strong, fine to medium granular structure. Consistence is very friable or friable.

The Bw horizon has hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 3 to 6. Texture is silt loam or very fine sandy loam. It has weak or moderate, fine or medium granular or subangular blocky structure. Some pedons have platy structure. Consistence is very friable or friable.

The BC horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 3 to 6. Some pedons have a BCg horizon below 20 inches with a chroma of 2. Texture is silt loam or very fine sandy loam. It has weak fine or medium granular structure. Consistence is very friable or friable.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 4. Texture is silt loam, very fine sandy loam, or loamy very fine sand. In some pedons below a depth of 40 inches there are strata ranging from silt loam to fine gravel. It is massive or single grain, depending upon texture. Consistence ranges from loose to friable.

Cosad Series

This taxadjunct of the Cosad series consists of very deep, somewhat poorly drained soils on deltas and beach ridges in the Champlain Valley. Cosad soils formed in sandy sediments underlain by clayey lacustrine or marine sediments. Slopes range from 0 to 8 percent.

Cosad soils are associated on the landscape with Claverack, Kingsbury, Covington, Deerfield, Stafford, Amenia, and Farmington soils. Claverack soils are moderately well drained. Kingsbury soils are clayey throughout. Covington soils are clayey throughout and are poorly drained. Deerfield soils are sandy throughout and moderately well drained. Stafford soils are sandy throughout. Amenia soils are loamy and are moderately well drained. Farmington soils are loamy, shallow to limestone bedrock, and well drained.

Typical pedon of Cosad loamy fine sand, 0 to 3 percent slopes, in the town of Essex, 300 feet south of the point on State Route 22 that is located 3/4 miles west of the junction of Route 22 and Lakeshore Road, in an abandoned hay field; USGS Willsboro 15 min quadrangle; NAD 1927; lat. 44 degrees 18 minutes 31 seconds N. and long. 73 degrees 21 minutes 55 seconds W.

Ap—0 to 12 inches, very dark grayish brown (10YR 3/2) loamy fine sand; light brownish gray (10YR 6/2) dry; weak fine and medium granular structure; very friable; many fine and common medium roots; slightly acid; clear wavy boundary.

Bw1—12 to 18 inches, light yellowish brown (10YR 6/4) fine sand; weak fine and medium subangular blocky structure; very friable; common fine and few medium roots; few macropores, 1/4 inch diameter; common fine and medium distinct strong brown (7.5YR 5/6) soft masses of iron accumulation and few fine distinct light gray (2.5Y 7/2) iron depletions; neutral; abrupt wavy boundary.

Bw2—18 to 23 inches, light yellowish brown (2.5Y 6/4) fine sand; weak fine and medium subangular blocky structure; very friable; few fine roots; few macropores; common fine prominent strong brown (7.5YR 4/6) soft masses of iron accumulation and few fine distinct light brownish gray (10YR 6/2) iron depletions; neutral; abrupt wavy boundary.

Bw3—23 to 25 inches, yellowish brown (10YR 5/4) loamy fine sand; weak fine and medium subangular blocky structure; friable; few fine roots; few fine tubular and common fine vesicular pores; many fine and medium distinct brown (7.5YR 4/4) and prominent reddish brown (5YR 4/4) soft masses of iron accumulation; slightly alkaline; abrupt smooth boundary.

2BC—25 to 39 inches, grayish brown (10YR 5/2) clay; weak medium and coarse prismatic structure; firm; few fine roots; common fine vesicular and few fine tubular pores; few thin discontinuous clay films on ped faces and in pore linings; many fine and medium distinct dark brown (7.5YR 4/4) and many fine and medium distinct brown (7.5YR 5/4) soft masses of iron accumulation and few fine prominent gray (5Y 6/1) iron depletions; slightly alkaline; clear irregular boundary.

2C—39 to 72 inches, 50 percent reddish gray (5YR 5/2) and 50 percent gray (10YR 5/1) clay; massive with coarse desiccation cracks; firm; few fine vesicular and tubular pores; common medium prominent yellowish brown (10YR 5/4) soft masses of iron accumulation; moderately alkaline, strongly effervescent.

The thickness of the solum ranges from 18 to 40 inches and usually corresponds to the thickness of the sandy upper deposit. Depth to bedrock is greater than 60 inches. The soil contains few or no rock fragments. Soil reaction ranges from strongly acid to slightly acid in the A horizon, strongly acid to neutral in the upper part of the B horizon, moderately acid to slightly alkaline in the lower part of the B horizon, and from neutral to moderately alkaline in the 2C horizon which is usually calcareous.

The Ap or A horizons have hue of 7.5YR to 2.5Y, value of 2 or 3, 5 or 6 dry, and chroma of 1 or 2, or they are neutral in color. Texture is fine sandy loam, loamy fine sand, loamy sand or sand. They have weak or moderate granular structure and very friable or friable consistence.

The B horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 4. It has few to common redoximorphic concentrations and depletions. Depletions are chroma 2 or less above a depth of 18 inches. Texture is loamy fine sand to sand. The B horizon is structureless or has weak, very fine to coarse subangular blocky or medium to very thick platy structure.

Some pedons have a 2BC horizon with colors similar to the 2C horizon. Texture is clay loam, silty clay loam, silty clay, or clay. It is massive or has weak coarse or medium prismatic structure.

The 2C horizon has hue of 2.5YR to 5GY, value of 3 to 6, and chroma of 1 to 4. Texture is silty clay loam, silty clay or clay. The 2C horizon is massive, or has weak or moderate medium to very thick plate-like divisions as depositional varves. Below depths of 40 inches thin lamina of silt and very fine sand are common.

Correlation Note: The CuA and CuB map units are taxadjuncts to the Cosad series because the pedon qualifies as having a Cambic horizon in the 2BC horizon. The classification of the taxadjunct is Sandy over clayey, mixed, superactive,

mesic Aquic Eutrudepts. The classification of Cosad is Sandy over clayey, mixed, superactive, nonacid, mesic Aquic Udorthents. This should not significantly affect use and management on a local basis for most purposes.

Couchsachraga Series

The Couchsachraga series consists of very shallow, somewhat excessively drained and excessively drained soils on summits, shoulders, and back slopes of glaciated mountains in the Adirondack High Peaks Area. These soils formed in sandy materials deposited by glacial ice or sandy residuum, and are underlain by meta-igneous bedrock. Slopes range from 15 to 80 percent.

Couchsachraga soils are associated on the landscape with Andic Cryaquods, Esther, Ricker, Santanoni, Skylight, and Wallface soils. Andic Cryaquods soils are loamy, very deep, and somewhat poorly drained. Esther soils are loamy, very deep, and moderately well drained. Santanoni soils are sandy and gravelly, and moderately deep to meta-igneous bedrock. Wallface soils are loamy, moderately deep to meta-igneous bedrock, and well drained. Skylight soils are shallow to meta-igneous bedrock. Ricker soils formed from organic material, are very shallow and shallow to meta-igneous bedrock, and well drained to excessively drained.

Typical pedon of Couchsachraga coarse sand, in a map unit of Ricker-Couchsachraga-Skylight complex, 35 to 80 percent slopes, very rocky, very bouldery, in the town of Newcomb, south-east facing slide areas of Cliff Mountain, 1,300 feet due north of a point on Upper Twin Brook that is 1.4 miles upstream from the junction of upper and Lower Twin Brook, 300 feet up the slide face; USGS Mt. Marcy topographic quadrangle; NAD 1927; lat. 44 degrees 05 minutes 38 seconds N. and long. 73 degrees 58 minutes 46 seconds W.

Oe—0 to 2 inches; dark reddish brown (5YR 3/2) moderately decomposed (hemic) plant material composed of conifer needles, leaves, and twigs; weak fine and medium granular structure; very friable; many very fine and fine, and few medium roots; extremely acid; clear wavy boundary.

Oa—2 to 4 inches; reddish black (2.5YR 2.5/1) highly decomposed (sapric) plant material; 25 percent stripped sand grains; weak fine and medium granular structure; very friable; many very fine and fine, and few medium roots; extremely acid; gradual wavy boundary. (Combined thickness of the O horizons is 2 to 20 inches.)

Bhs—4 to 9 inches; black (5YR 2.5/1) coarse sand; weak fine and medium granular structure; friable; strongly smeary; common very fine and fine and few medium roots; 14 percent gravel; extremely acid; abrupt wavy boundary. (4 to 10 inches thick)

R—9 inches; Marcy anorthosite bedrock.

Depth to bedrock ranges from 4 to 10 inches from the mineral soil surface. Rock fragment content ranges from 0 to 35 percent by volume throughout the solum. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. It is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) material. It has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

Some pedons have an E horizon that has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand, or coarse sand in the fine-earth fraction. It has weak fine or medium granular or subangular blocky structure, or is single grain. Consistence is very friable, friable, or loose.

The Bhs horizons and Bh horizons (where present), have hue of 10R to 7.5YR or, with value and chroma of 3 or less. Texture is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand, or coarse sand in the fine-earth fraction. The horizons have weak or moderate, fine, medium, or coarse granular or subangular blocky structure, or are single grain. Consistence is very friable, friable, or loose. It is moderately or strongly smeary.

Bedrock is anorthositic gneiss (metamorphosed anorthosite).

Covington Series

The Covington series consists of very deep, poorly drained soils in depressions on lake plains in the Champlain Valley. Covington soils formed in clayey sediments deposited in still water that was fresh or brackish. Slopes range from 0 to 3 percent.

Covington soils are associated on the landscape with Vergennes, Kingsbury, Livingston, Cayuga, Cosad, and Nellis soils. Vergennes soils are moderately well drained. Kingsbury soils are somewhat poorly drained. Livingston soils are very poorly drained. Cayuga soils are clayey over loamy and are moderately well drained. Cosad soils are sandy over clayey and are somewhat poorly drained. Nellis soils are loamy and well drained.

Typical pedon of Covington clay, 0 to 3 percent slopes, next to a hay field, in the town of Willsboro, 1,050 feet east of a point on Willsboro Point Road, that is 2,000 feet north of the junction of Willsboro Point Road and Mouth of River Road; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 22 minutes 42 seconds N. and long. 73 degrees 22 minutes 40 seconds W.

Ap—0 to 9 inches, black (10YR 2/1) clay; moderate medium and fine subangular blocky parting to weak medium and fine granular structure; friable, sticky and very plastic; many very fine and few fine roots; neutral; abrupt smooth boundary.

Btg1—9 to 19 inches, dark gray (10YR 4/1) clay; moderate coarse prismatic parting to moderate coarse and medium angular blocky structure; firm, very sticky and very plastic; common very fine roots; common thick clay films on ped surfaces; common fine distinct yellowish brown (10YR 5/6) and many medium distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation, and few fine black (2.5Y 2.5/1) soft masses of manganese accumulation; neutral; clear wavy boundary.

Btg2—19 to 24 inches, dark gray (10YR 4/1) clay; few light olive brown (2.5Y 5/4) silt and very fine sand coatings on ped faces; weak coarse prismatic parting to moderate coarse and medium angular blocky structure; firm, very sticky and very plastic; few very fine roots; common moderately thick clay films on ped surfaces; few medium distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation; neutral; clear smooth boundary.

BCg—24 to 36 inches, dark gray (10YR 4/1) clay; common light olive brown (2.5Y 5/4) silt and very fine sand coatings on ped faces; weak thick platy parting to moderate fine and medium angular blocky structure; firm, very sticky and very plastic; few very fine roots; few 15-20 mm reddish brown (5YR 4/3) clay nodules; many fine distinct dark yellowish brown (10YR 4/4) and few medium and fine distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral; clear smooth boundary.

C—36 to 70 inches, dark grayish brown (2.5Y 4/2) clay; fracture surfaces are dark gray (N 4/0); massive with desiccation cracks; firm; very sticky and very plastic; many medium distinct very pale brown (10YR 7/3) secondary CaCo3 accumulations; few fine distinct yellowish brown (10YR 5/6) and many fine faint olive brown (2.5Y 4/4) soft masses of iron accumulation; moderately alkaline, strongly effervescent.

The thickness of the solum ranges from 20 to 40 inches. Depth to the calcareous material ranges from 20 to 60 inches. Depth to contrasting strata or bedrock is more

than 60 inches. Rock fragments range from 0 to 5 percent. Reaction ranges from moderately acid to neutral in the surface layer, moderately acid to slightly alkaline in the subsoil, and moderately acid to moderately alkaline in the substratum.

The Ap horizon has hue of 10YR or 2.5Y, value of 2 to 3 moist and 5.5 or less dry, and chroma of 1 or 2. Texture is clay, silty clay, silty clay loam, or clay loam. Structure is moderate to strong, medium to coarse granular or moderate to strong, very fine to medium subangular blocky. Consistence is friable, firm, plastic, or sticky.

The BA and B horizons have hue of 7.5YR to 5Y, value of 3 to 5, and chroma of 1 or 2. Redoximorphic features of higher chroma range from few to many and distinct to prominent. Texture is clay with thin strata or subhorizons of silty clay. Structure is weak to strong, coarse prismatic that parts to moderate or strong, very fine to coarse angular blocky or it is weak or moderate, thin to thick platy. Consistence is firm, very firm, very plastic, or very sticky.

The C horizon is neutral or has hue of 2.5Y or 5Y, value of 3 to 5, and chroma of 0 to 2. Redoximorphic features with higher chroma range from few to many and distinct to prominent. Texture is clay or silty clay, but silt and silt loam varves alternate with clay varves in some pedons. Structure is weak or moderate, medium or coarse prismatic that parts to weak or moderate, fine to coarse angular blocky or it is massive. Consistence is firm, very firm, very plastic, or very sticky.

Croghan Series

The Croghan series consists of very deep, moderately well drained sandy soils on deltas, outwash plains, outwash terraces, and high stream terraces in the Adirondack Upland. Croghan soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 8 percent.

Croghan soils are associated on the landscape with Adams, Naumburg, Searsport, Rumney, Burnt Vly, and Monadnock soils. Adams soils are somewhat excessively drained. Naumburg soils are somewhat poorly drained. Searsport soils are very poorly drained. Rumney soils are loamy and poorly drained. Burnt Vly soils are mucky and very poorly drained. Monadnock soils are loamy over sandy or sandy-skeletal and are well drained.

Typical pedon of Croghan fine sand, 0 to 3 percent slopes, in forested area, in the town of Wilmington, O.54 miles east on Perkins Road from intersection with Hardy-Kilburn Road, then 900 feet south on trail, then 60 feet west in a stand of White Pine; USGS Lake Placid 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 22 minutes 15 seconds N. and long. 73 degrees 47 minutes 22 seconds W.

Oi—0 to 1 inch, slightly decomposed plant material.

A—1 to 3 inches, very dark grayish brown (10YR 3/2) fine sand; weak fine granular structure; very friable; many very fine and fine, and common medium and coarse roots; 2 percent rock fragments; very strongly acid; clear wavy boundary.

E—3 to 5 inches, gray (7.5YR 5/1) fine sand; single grain; loose; many very fine and common fine, medium, and coarse roots; 2 percent rock fragments; strongly acid; abrupt wavy boundary.

Bhs—5 to 8 inches, dark reddish brown (5YR 3/3) fine sand; weak fine and medium subangular blocky structure; friable; 20 percent dark reddish brown (5YR 3/3 & 3/2) very firm and brittle ortstein nodules 1/2 to 2 inches in diameter; common very fine, fine, medium, and few coarse roots; 2 percent rock fragments; strongly acid; clear irregular boundary.

Bs1—8 to 14 inches, brown (7.5YR 4/4) fine sand; weak fine and medium subangular blocky structure; friable; 20 percent dark reddish brown (5YR 3/3 & 3/2) very firm and brittle ortstein nodules 1/2 to 2 inches in diameter; common very fine, fine, medium, and few coarse roots; 2 percent rock fragments; strongly acid; clear wavy boundary.

Bs2—14 to 23 inches, dark yellowish brown (10YR 4/4) fine sand; weak medium subangular blocky structure; very friable; 5 percent dark reddish brown (5YR 3/3 & 3/2) ortstein nodules 1/8 to 1/2 inch in diameter; few very fine, fine, medium, and coarse roots; 2 percent rock fragments; strongly acid; gradual wavy boundary.

BC—23 to 29 inches, yellowish brown (10YR 5/4) sand; single grain and weak medium subangular blocky structure; loose and very friable; few very fine, fine, medium, and coarse roots; 10 percent rock fragments; common coarse distinct strong brown (7.5YR 5/8) masses of iron accumulation, and common medium distinct grayish brown (10YR 5/2) iron depletions; moderately acid; clear wavy boundary.

C1—29 to 42 inches, pale brown (10YR 6/3) sand; single grain; loose; 5 percent rock fragments; common fine prominent strong brown (7.5YR 5/8) masses of iron accumulation, and common medium distinct gray (10YR 6/1) iron depletions; moderately acid; abrupt wavy boundary.

C2—42 to 45 inches, grayish brown (10YR 5/2) loamy fine sand with thin strata of fine sandy loam; massive; very friable; common very fine pores; common medium prominent reddish brown (5YR 4/4) masses of iron accumulation; moderately acid; abrupt wavy boundary.

C3—45 to 72 inches, grayish brown (2.5Y 5/2) sand; single grain; loose; 6 percent rock fragments; common fine prominent yellowish brown (10YR 5/6) masses of iron accumulation; moderately acid.

The mineral solum thickness ranges from 20 to 50 inches. Textures are predominantly sandy but include fine sandy loam within a depth of 10 inches from the mineral soil surface which can include all or part of the A horizon, the E horizon, if present, and the upper part of the B horizon. Depth to bedrock is greater than 60 inches. Redoximorphic features occur within 30 inches of the mineral soil surface. Rock fragments range from 0 to 5 percent by volume in the surface and subsurface, and from 0 to 15 percent in the subsoil and substratum.

The O horizon has hue of 5YR to 10YR or is neutral, with value of 2 to 3 and chroma of 0 to 3. It is slightly to highly decomposed plant material. Reaction ranges from extremely acid to moderately acid.

The A horizon has hue of 5YR to 10YR, value of 2 to 4 and chroma of 1 or 2. Ap horizons include value of 5 and chroma of 3, and are up to 13 inches thick. Texture is fine sandy loam, loamy fine sand, loamy sand, fine sand or sand. Reaction ranges from extremely acid to moderately acid. Some pedons have an A/E horizon.

The E horizon has hue of 5YR to 10YR, value of 5 to 7, and chroma of 1 or 2. Texture is fine sandy loam, loamy fine sand, loamy sand, fine sand or sand. Reaction ranges from extremely acid to moderately acid.

The Bhs horizon has hue of 2.5YR to 7.5YR, with value and chroma of 3 or less. Texture is fine sandy loam, loamy fine sand, loamy sand, fine sand or sand. Reaction ranges from very strongly acid to moderately acid.

Some pedons have a Bh horizon that has hue of 5YR to 10YR, value of 2 to 3 and chroma of 1 to 4. The horizon is up to 3 inches thick. Texture and reaction ranges are the same as the Bhs.

The Bs horizon has hue of 2.5YR to 10YR, value of 2.5 to 6, and chroma of 3 to 8. Texture is fine sandy loam, loamy fine sand, loamy sand, fine sand or sand. Reaction ranges from very strongly acid to moderately acid.

The BC horizon, where present, has hue of 7.5YR to 2.5Y, value of 4 to 8, and chroma of 2 to 6. Texture is loamy fine sand, loamy sand, fine sand or sand. Reaction ranges from very strongly acid to moderately acid.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 7, and chroma of 1 to 6. Texture is loamy fine sand, loamy sand, fine sand, sand, or coarse sand. Thin strata of very fine sandy loam or fine sandy loam are present in some pedons below a depth of 40 inches. Reaction ranges from very strongly acid to moderately acid.

Deerfield Series

The Deerfield series consists of very deep, moderately well drained soils on deltas in the Champlain Valley. Deerfield soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 8 percent.

Deerfield soils are associated on the landscape with Windsor, Stafford, Gougeville, Claverack, Kingsbury, Howard, and Nellis soils. Windsor soils are excessively drained. Stafford soils are somewhat poorly drained. Gougeville soils are poorly drained. Claverack soils are sandy over clayey. Kingsbury soils are clayey and somewhat poorly drained. Howard soils are gravelly and are well drained to excessively drained. Nellis soils are loamy and are well drained.

Typical pedon of Deerfield loamy sand, 0 to 3 percent slopes, in the town of Chesterfield, 400 feet north on U.S. Route 9 from where it crosses Mud Brook (2 miles south of Keeseville), then 100 feet east of the highway, in a pasture; USGS Willsboro, NY 15 minute quadrangle; NAD 1927; lat. 44 degrees 28 minutes 52 seconds N. and long. 73 degrees 29 minutes 12 seconds W.

Ap—0 to 10 inches, very dark gray (10YR 3/1) loamy sand; pale brown (10YR 6/3) dry; moderate fine and medium granular structure; friable; many fine and very fine roots; moderately acid; abrupt smooth boundary.

Bw1—10 to 15 inches, yellowish brown (10YR 5/6) sand; single grain; loose; few fine and very fine roots; moderately acid; clear smooth boundary.

Bw2—15 to 30 inches, yellowish brown (10YR 5/4) sand; single grain; loose; few medium distinct light gray (10YR 7/2) iron depletions and few medium prominent strong brown (7.5YR 5/8) soft masses of iron accumulation in the lower part; moderately acid; clear smooth boundary.

C—30 to 72 inches, dark grayish brown (10YR 4/2) sand; single grain; loose; moderately acid.

The thickness of the solum ranges from 15 to 40 inches. Gravel, generally fine pebbles, ranges from 0 to 15 percent in the solum and 0 to 20 percent in the substratum. Reaction ranges from very strongly acid to slightly acid unless limed. Iron depletions with chroma of two or less are between depths of 15 and 40 inches from the mineral soil surface.

The Ap horizon has hue of 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is fine sandy loam, sandy loam, loamy fine sand, loamy sand, fine sand, or sand. Undisturbed pedons commonly have an 0 horizon, and a thin sequence of A, E, and Bs, Bhs or Bh horizons, or an AB horizon. The Ap or A horizon has weak or moderate very fine to medium granular structure.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 3 to 6. Texture of the upper part of the Bw horizon, within a depth of 10 inches from the soil surface, has the same range as the A horizon. Below 10 inches texture is loamy fine sand, loamy sand, fine sand, sand or coarse sand. Structure is weak, very fine to medium granular or subangular blocky, or is single grain.

The BC horizon, where present, has hue of 7.5YR to 2.5Y, value of 3 to 6, and chroma of 2 to 4. Texture range is the same as the lower part of the Bw horizon. Structure is weak, very fine to medium granular, or is single grain.

The C horizon has hue of 7.5YR to 5Y, value of 4 to 6, and chroma of 1 to 4. Texture is loamy fine sand, loamy sand, fine sand, sand or coarse sand. It is commonly single grain but may be very weak or weak granular.

Correlation Note: The DeA and DeB map units have moderate structure in the Ap horizon which is stronger than allowed in the range of the Deerfield series. This should not significantly affect use and management on a local basis for most purposes.

Depeyster Series

The Depeyster series consists of very deep, moderately well drained soils on lacustrine terraces in intermontane valleys of the Adirondack Uplands. Depeyster soils formed in silty clay sediments deposited in still water. Slopes range from 8 to 25 percent.

Depeyster soils are associated on the landscape with Hailesboro, Adams, Champlain, Becket, Tunbridge, Monadnock, and Medomak soils. Hailesboro soils are somewhat poorly drained. Adams and Champlain soils are sandy and are somewhat excessively drained. Becket soils are loamy and well drained. Tunbridge soils are loamy, well drained, and moderately deep to meta-igneous bedrock. Monadnock soils are loamy over sandy or gravelly and are well drained. Medomak soils are silty and are very poorly drained.

Typical pedon of Depeyster silt loam, 15 to 25 percent slope, in a hayfield, town of Jay, about 1,000 feet north of the junction of Springfield Road and Route 9N; USGS Lake Placid 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 20 minutes 26 seconds N. and long. 73 degrees 46 minutes 34 seconds W.

Ap—0 to 4 inches, dark grayish brown (10YR 4/2) silt loam; moderate medium granular structure; friable; many fine and very fine roots; slightly acid; clear smooth boundary.

E—4 to 7 inches, 70 percent grayish brown (10YR 5/2) and 30 percent light brownish gray (10YR 6/2) silt loam; moderate medium subangular blocky structure; friable; common very fine roots; very few very fine tubular pores; neutral; gradual smooth boundary.

Bt/E—7 to 13 inches, 70 percent brown (10YR 4/3) (B part), and 30 percent grayish brown (10YR 5/2) (E part) silt loam; moderate medium subangular blocky structure; friable; common very fine roots; few discontinuous clay films along ped faces; very few very fine tubular pores; neutral; gradual smooth boundary.

Bt1—13 to 18 inches, brown (10YR 4/3) silt loam; friable; few very fine roots; thick continuous brown (7.5YR 4/4) clay films on ped faces and in pores; common very fine tubular and vesicular pores; few medium faint light brownish gray (10YR 6/2) iron depletions in lower part; neutral; gradual smooth boundary.

Bt2—18 to 25 inches, brown (10YR 4/3) silt loam; moderate medium subangular blocky structure; friable; few very fine roots; thick continuous light brownish gray (10YR 6/2) clay films on ped faces and in pores; very few very fine tubular pores; neutral; gradual smooth boundary.

C1—25 to 31 inches, brown (10YR 4/3) silt loam; massive, varved; firm; few very fine roots; pockets of reddish brown (5YR 4/4) silty clay loam; few very fine tubular pores; common medium faint grayish brown (10YR 5/2) iron depletions; slightly alkaline; gradual smooth boundary.

C2—31 to 72 inches, brown (10YR 4/3) silt loam; massive, varved; firm; few very fine tubular pores; many medium faint light brownish gray (10YR 6/2) iron depletions; slightly effervescent, slightly alkaline.

The thickness of solum ranges from 24 to 45 inches. Bedrock is deeper than 60 inches. Depth to carbonates ranges from 25 to 72 inches. Rock fragments range from 0 to 5 percent throughout.

The Ap horizon has hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 2 or 3. Texture is fine sandy loam, very fine sandy loam, or silt loam. It has weak or moderate granular or subangular blocky structure. Consistence is very friable or friable. Reaction is moderately acid to neutral.

Some pedons have an E horizon that have hue of 5YR to 2.5Y, value of 5 or 6, and chroma of 2 to 4. Texture is fine sandy loam, very fine sandy loam, or silt loam. Reaction is strongly acid to neutral.

The B/E horizon has colors and textures similar to the B and E horizons. The E part (albic material) must constitute 15 percent or more by volume of the horizon.

The Bt horizon has hue of 7.5YR to 2.5Y, value of 4 or 5, chroma of 3 or 4 above 30 inches, and chroma of 2 to 4 below 30 inches. Texture is silt loam or silty clay loam and some pedons have layers which range from fine sandy loam to silty clay. Redoximorphic features range from few to many and are low and high chroma. Reaction is slightly acid or neutral in the upper part and slightly acid to slightly alkaline in the lower part.

Some pedons have a CB horizon that has color, texture, and reaction characteristics that are mixtures of the overlying Bt and underlying C horizon.

The C horizon has hue of 10YR to 5YR, value of 4 or 5, and chroma of 2 to 8. Texture ranges from silty clay loam to stratified silt and very fine sand. Loamy till is at depths of 3.5 to 6 feet in some pedons. Reaction is neutral through moderately alkaline.

Dunkirk Series

The Dunkirk series consists of very deep, well drained soils on lacustrine terraces and lake plains in the Champlain Valley. Dunkirk soils formed in silty clay sediments deposited in still water. Slopes range from 8 to 60 percent.

Dunkirk soils are associated on the landscape with Collamer, Factoryville, Colonie, Chatfield, Hollis, Hartland, and Vergennes soils. Collamer soils are moderately well drained. Factoryville and Colonie soils are sandy and are well drained to somewhat excessively drained. Chatfield and Hollis soils are loamy and are 20 to 40 inches and 10 to 20 inches deep to meta-igneous bedrock respectively. Hartland soils are silty. Vergennes soils are clayey and are moderately well drained.

Typical pedon of Dunkirk silt loam, 8 to 15 percent slopes, in an abandoned hay field, in the town of Crown Point, 1,200 feet due southwest of the junction of Routes 9N and 22 and Sugar Hill Road, USGS Ticonderoga, NY 15 minute topographic quadrangle; NAD 1927; lat. 43 degrees 56 minutes 57 seconds N. and long. 73 degrees 26 minutes 07 seconds W.

Ap—0 to 6 inches, dark brown (10YR 3/3) silt loam; moderate fine and medium granular structure; friable; many fine and very fine and few medium roots; slightly acid; abrupt smooth boundary.

E—6 to 10 inches, pale brown (10YR 6/3) silt loam; moderate fine and medium subangular blocky structure; friable; many fine and very fine and few medium roots; few fine vesicular and tubular pores; common medium faint light yellowish brown (10YR 6/4) stripped sand grains along ped faces; slightly acid; clear smooth boundary.

E/B—10 to 15 inches, brown (10YR 5/3) silt loam; moderate fine and medium subangular blocky structure; friable; common fine and very fine roots; many fine tubular and common fine vesicular pores; few thin discontinuous clay films along root channels and on ped faces; 35 percent brown (10YR 4/3) ped interiors; slightly acid; clear smooth boundary.

B/E—15 to 21 inches, brown (10YR 4/3) silt loam with very pale brown (10YR 7/3) ped faces 1 to 2 mm thick (less than 15 percent E material); strong medium and coarse subangular blocky structure; friable; common fine roots; many fine tubular and common fine vesicular pores; common thin discontinuous clay films on ped faces and in root channels; neutral; clear wavy boundary.

Bt1—21 to 29 inches, brown (10YR 4/3) silty clay loam; strong medium and coarse subangular blocky structure; friable; few fine roots; many fine tubular and common fine vesicular pores; many moderately thick continuous clay films on ped faces and in pore linings; neutral; clear smooth boundary.

Bt2—29 to 35 inches, brown (10YR 4/3) silt loam; moderate thick platy parting to moderate medium subangular blocky structure; friable; few fine roots; many fine tubular and common fine vesicular pores; common thin discontinuous clay films on ped faces and root channels; neutral; clear smooth boundary.

BC—35 to 42 inches, dark yellowish brown (10YR 4/4) silt loam; weak thick platy structure; friable; few fine tubular and vesicular pores; neutral; clear smooth boundary.

C—42 to 72 inches, dark grayish brown (10YR 4/2) silty clay loam; moderate thin and medium platy structure (inherited from varves); firm; few fine tubular and vesicular pores; slightly alkaline, slightly effervescent.

The thickness of the solum ranges from 20 to 48 inches. Depth to carbonates ranges from 20 to 54 inches. Rock fragments, mainly gravel and cobbles, range from none to 5 percent throughout the soil. Depth to bedrock is greater than 60 inches.

The Ap or A horizon has hue of 7.5YR to 2.5Y, value of 3 to 5 and chroma of 2 to 4. Texture is silt loam, very fine sandy loam or fine sandy loam. The horizon is friable or very friable, and reaction ranges from strongly acid to slightly acid, unless limed.

The EB horizon has hue of 7.5YR to 2.5Y, value of 5 or 6, and chroma of 3 to 5. Texture ranges from silt loam to fine sandy loam. Structure is subangular blocky or platy, and consistence is friable or very friable. Reaction ranges from strongly acid to neutral.

Some pedons have an E horizon with value of 5 to 7 and chroma of 2 or 3. Texture is similar to the EB horizon.

The E/B and B/E horizon have color and texture similar to the respective portion of the E or EB and Bt horizon above and below.

The Bt horizon has hue of 5YR to 2.5Y, value of 3 through 5 and chroma from 2 through 4, with the lowest chroma being inherited from weathered dark shale. Texture is silt loam, very fine sandy loam, or silty clay loam. In some pedons, the Bt horizon has faint redoximorphic features in the lower part. Consistence is friable or firm. Reaction ranges from moderately acid to slightly alkaline.

Some pedons have a BC horizon that is slightly acid to moderately alkaline and has a lower clay content than the overlying Bt horizon.

The C horizon has colors similar to the Bt horizons. Texture ranges from very fine sand or silt to silty clay loam, some pedons having thin strata of finer or coarser texture including sand and gravel below depths of 4 feet. Reaction ranges from slightly acid to moderately alkaline.

Duxbury Series

The Duxbury series consists of very deep, well drained soils on outwash plains, outwash terraces, kame terraces, and high stream terraces in the Adirondack Upland. Duxbury soils formed in stratified, water deposited, loamy sediments underlain by gravelly or sandy sediments. Slopes range from 3 to 15 percent.

Duxbury soils are associated on the landscape with Adams, Becket, Monadnock, Tunbridge, Rumney, and Burnt Vly soils. Adams soils are sandy in the solum and are somewhat excessively drained. Becket soils are loamy throughout and have a dense substratum. Monadnock soils were deposited by glacial ice. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock. Rumney soils are loamy throughout and are poorly drained. Burnt Vly soils are mucky and are very poorly drained.

Typical pedon of Duxbury fine sandy loam, 3 to 15 percent slopes, in a wooded area, in the town of North Elba, 3,200 feet east of a point on Heart Lake Rd., that is 2.3 miles south of the junction of Heart Lake Rd and NYS Route 73; USGS Mount Marcy 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 12 minutes, 44 seconds N. and long. 73 degrees, 57 minutes, 58 seconds W.

Oe—0 to 2 inches; moderately decomposed leaf, needle, and twig material; many fine roots.

A—2 to 4 inches; black (7.5YR 2.5/1) fine sandy loam; moderate medium granular structure; friable; many fine and very fine roots; extremely acid; clear wavy boundary.

E—4 to 5 inches; light brownish gray (10YR 6/2) fine sandy loam; weak fine granular structure; very friable; many fine and very fine roots; 2 percent rock fragments; very strongly acid; clear broken boundary.

Bhs—5 to 13 inches; dark reddish brown (5YR 3/3) fine sandy loam; moderate medium subangular blocky structure; friable; many fine and very fine roots; 2 percent rock fragments; moderately acid; clear wavy boundary.

Bs—13 to 21 inches; dark brown (7.5YR 3/4) fine sandy loam; moderate medium subangular blocky structure; friable; common fine and very fine roots; 10 percent rock fragments; moderately acid; clear wavy boundary.

2C1—21 to 31 inches; light olive brown (2.5Y 5/4) gravelly fine and medium sand; single grain; loose; few fine roots; 20 percent rock fragments; slightly acid; clear wavy boundary.

2C2—31 to 36 inches; light olive brown (2.5Y 5/4) gravelly coarse sand; single grain; loose; 25 percent rock fragments; slightly acid; clear wavy boundary.

2C3—36 to 72 inches; olive brown (2.5Y 4/4) very gravelly coarse sand; single grain; loose; 35 percent rock fragments; slightly acid.

The thickness of the mineral solum and depth to the 2C horizon range from 16 to 30 inches. Depth to bedrock is more than 60 inches. Rock fragments are mostly gravel and cobbles and typically range from 0 to 20 percent in the mineral solum and from 15 to 70 percent in the substratum, but the weighted average in the particle size control section is less than 35 percent. Some pedons have subhorizons of the substratum that have less than 15 percent rock fragments. Reaction ranges from extremely acid to slightly acid in the upper part of the mineral solum and from very strongly acid to slightly acid in the lower part of the solum and in the substratum.

Some pedons have an A horizon with hue of 5YR, 7.5YR or 10YR, value of 2 to 3, and chroma of 1 to 4. Some pedons have an Ap horizon with hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 2 to 4. The A or Ap horizon is fine sandy loam, very fine sandy loam, or silt loam in the fine-earth fraction.

The E horizon has hue of 7.5YR or 10YR, value of 5 or 6, and chroma of 1 or 2. Texture is fine sandy loam or very fine sandy loam in the fine-earth fraction.

The Bhs horizon is neutral or has hue of 2.5YR to 7.5YR, with value and chroma of 3 or less. Some pedons have a Bh horizon that is neutral or has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 0 to 2. The Bs horizon has hue of 5YR to 10YR, with value or chroma of 4 or more. The Bhs and Bh horizons are silt loam, loam, very fine sandy loam, or fine sandy loam in the fine-earth fraction. The Bs horizon is silt loam, loam, very fine sandy loam, fine sandy loam, or loamy fine sand in the fine-earth fraction.

The BC horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture range is the same as the Bs horizon.

The 2C horizon has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Texture is loamy sand, sand, or fine to coarse sand in the fine-earth fraction.

Elmridge Series

The Elmridge series consists of very deep, moderately well drained soils on lake plains and deltas in the Champlain Valley. Elmridge soils formed in loamy sediments underlain by clayey lacustrine or marine sediments. Slopes range from 2 to 8 percent.

Elmridge soils are associated on the landscape with Vergennes, Kingsbury, Claverack, Nellis, Amenia, Chatfield, and Hollis soils. Vergennes soils are clayey

throughout. Kingsbury soils are clayey throughout and are somewhat poorly drained. Claverack soils are sandy over clayey. Nellis soils are loamy throughout and are well drained. Amenia soils are loamy throughout. Chatfield and Hollis soils are loamy, well drained, and are 20 to 40 inches and 10 to 20 inches deep respectively to meta-igneous bedrock.

Typical pedon of Elmridge fine sandy loam, 2 to 8 percent slopes, in a hay field, in the town of Westport, 65 feet south of a point on State Route 9N that is 1,650 feet east of the junction of Route 9N and Fitzgerald Road; USGS Port Henry 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 12 minutes 02 seconds N. and long. 73 degrees 29 minutes 06 seconds W.

Ap—0 to 8 inches, dark brown (10YR 3/3) fine sandy loam; pale brown (10YR 6/3) dry; weak fine and medium granular structure; very friable; many very fine roots; common fine tubular and vesicular pores; 1 percent rock fragments; moderately acid; abrupt smooth boundary.

Bw1—8 to 15 inches, yellowish brown (10YR 5/4) fine sandy loam; weak medium and coarse subangular blocky structure; friable; many very fine roots; common fine tubular and vesicular pores; 1 percent rock fragments; few medium faint brown (10YR 5/3) and few fine and medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; moderately acid; gradual wavy boundary.

Bw2—15 to 25 inches, dark yellowish brown (10YR 4/4) loam; weak fine subangular blocky structure; friable; common very fine roots; common fine and medium tubular pores; common medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation, and common medium distinct grayish brown (10YR 5/2) iron depletions; slightly acid; clear wavy boundary.

2BC—25 to 31 inches, dark brown (10YR 3/3) silty clay loam; weak medium and thick platy parting to weak fine subangular blocky structure; firm; common very fine roots; few fine tubular pores; few fine prominent light gray (10YR 7/2) silt coats on ped faces; many medium distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulations, and many medium distinct gray (10YR 6/1) iron depletions; slightly acid; abrupt wavy boundary.

2C1—31 to 46 inches, dark grayish brown (10YR 4/2) silty clay loam; gray (10YR 5/1) ped faces; massive with moderately thick and very thick plate-like divisions; firm; few very fine roots along desiccation cracks; few fine tubular pores; 1 percent rock fragments; common medium distinct dark yellowish brown (10YR 4/4) and common medium prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; few fine distinct black (10YR 2/1) soft masses of manganese accumulation; neutral; clear wavy boundary.

2C2—46 to 72 inches, 60 percent dark grayish brown (10YR 4/2) and 40 percent dark yellowish brown (10YR 4/4) silty clay; massive, varved; firm; few fine tubular pores; 1 percent rock fragments; common fine faint brown (10YR 4/3) soft masses of iron accumulation; few fine distinct black (10YR 2/1) soft masses of manganese accumulation; neutral.

The thickness of the solum and depth to the underlying clayey material range from 18 to 40 inches. Rock fragments, mostly fine gravel, range from 0 to 5 percent by volume in the upper loamy horizons and from 0 to 2 percent in the underlying clayey horizons. Reaction ranges from very strongly acid to neutral in the A horizon, from strongly acid to neutral in the B horizon with at least one subhorizon being moderately acid, slightly acid, or neutral, and from moderately acid to slightly alkaline in the 2C horizon. Depth to carbonates is greater than 40 inches.

The Ap horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Dry value is 6 or more. Undisturbed pedons have a thin A horizon with value of 2 or 3 and chroma of 1 to 3. The Ap or A horizon is sandy loam, fine sandy loam, very fine sandy loam, or loam. Structure commonly is weak or moderate granular but includes

weak subangular blocky parting to granular in some pedons and is friable or very friable.

The upper part of the B horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 3 to 6. The lower part of the B horizon has hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 2 to 6. Subhorizons with matrix chroma of 2 are below a depth of 20 inches. The B horizon has iron depletions above a depth of 24 inches. Texture of the non-contrasting Bw horizon is sandy loam, fine sandy loam, or loam, but some pedons have thin strata or lenses of loamy sand, loamy fine sand, or loamy very fine sand. The loamy Bw horizon has weak or moderate granular or subangular blocky structure, or it is massive. Consistence is friable or very friable. Some pedons have a silty clay loam or silty clay 2Bw or 2BC horizon just above the 2C horizon. These contrasting horizons have weak or moderate blocky, platy, or prismatic structure. Consistence is friable or firm.

The 2C horizon commonly has hue of 7.5YR to 5Y, value of 4 to 6, and chroma of 2 to 4. The value is 3 in some places in the Champlain Valley of New York. In some pedons the chroma is 1. It typically has redoximorphic features. Texture is silty clay loam, silty clay, or clay. Some pedons have thin lenses or thin coatings of silt, very fine sand, or fine sand on ped surfaces. In some pedons below 40 inches, there are thin to thick lenses of very fine sandy loam or fine sandy loam. The 2C horizon is massive or appears in the form of plates or weak prisms. Consistence is firm or very firm.

Esther Series

Esther soils consist of very deep, moderately well drained soils on back slopes and footslopes of glaciated mountains in the Adirondack High Peaks Area. These soils formed in loamy materials underlain by compact, loamy, very firm lodgment till. Slopes range from 3 to 35 percent.

Esther soils are associated on the landscape with Andic Cryaquods, Couchsachraga, Ricker, Santanoni, Skylight, and Wallface soils. Andic Cryaquods soils are somewhat poorly drained. Couchsachraga soils are sandy, 4 to 10 inches deep to meta-igneous bedrock, and are somewhat excessively drained and excessively drained. Ricker soils are organic, 1 to 20 inches deep to meta-igneous bedrock, and are well drained to excessively drained. Santanoni soils are sandy and gravelly, 20 to 40 inches deep to meta-igneous bedrock and are somewhat excessively drained and excessively drained. Skylight soils are sandy, 10 to 20 inches deep to meta-igneous bedrock, and are somewhat excessively drained and excessively drained. Wallface soils are 20 to 40 inches deep to meta-igneous bedrock and are well drained (fig. 37).

Typical pedon of Esther fine sandy loam, in a map unit of Esther-Wallface complex, 15 to 35 percent slopes, rocky, very bouldery, in a wooded area, in the town of Wilmington, about 11,000 feet up the Whiteface Mountain toll road from the toll booth, then 460 feet due west down slope; USGS Lake Placid 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees, 23 minutes, 06 seconds N. and long. 73 degrees, 54 minutes, 09 seconds W.

Oi—0 to 1 inch; very dark brown (7.5YR 2.5/2) slightly decomposed (fibric) plant material; 95 percent unrubbed fiber, 60 percent rubbed fiber; weak medium granular structure; very friable; many very fine and fine roots; extremely acid; clear smooth boundary.

Oe—1 to 4 inches; black (7.5YR 2.5/1) moderately decomposed (hemic) plant material; 60 percent unrubbed fiber, 12 percent rubbed fiber; weak fine granular structure; very friable; many very fine and fine, and common medium roots; extremely acid; clear wavy boundary.

Oa—4 to 8 inches; black (N 2.5/0) highly decomposed (sapric) plant material; 10 percent unrubbed fiber, 1 percent rubbed fiber, 5 percent fine sand; weak fine and medium granular structure; very friable; common fine and medium, and few

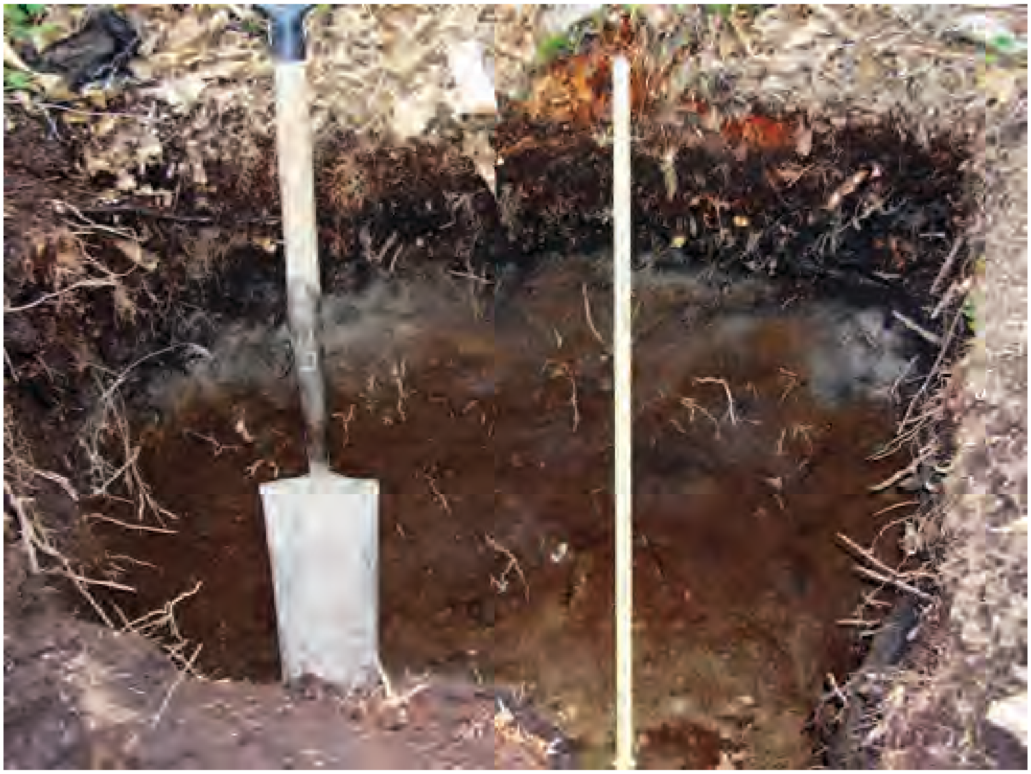

Figure 37.—Soil profile of the Esther series from a hand dug pit, in the town of Wilmington, in a spruce-fir forest. Note the thick layers of organic material over the well expressed gray, leached albic horizon in a soil that has reasonably good drainage. Oxides of iron and aluminum and organic matter are leached out of the albic horizon, and are deposited in the underlying highly acidic, dark reddish brown spodic (subsoil) horizon. Subsoil concentrations of organic matter, iron, and aluminum are very high in these mountainous areas above 3,000 feet in elevation. A very firm, dense, acidic till substratum derived from anorthositic gneiss lies in the bottom of the pit.

coarse roots; extremely acid; abrupt wavy boundary. (Combined thickness of the O horizons is 6 to 20 inches.)

E—8 to 10 inches; gray (5YR 5/1) fine sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and medium roots; 5 percent subrounded gravel; very strongly acid; abrupt wavy boundary (1 to 5 inches thick).

Bhs1—10 to 22 inches; dusky red (2.5YR 3/2) fine sandy loam; weak medium and coarse subangular blocky structure; friable, moderately smeary; common fine and medium roots; 10 percent subrounded gravel and 3 percent subrounded cobbles; very strongly acid; clear wavy boundary.

Bhs2—22 to 28 inches; dark reddish brown (2.5YR 3/3) gravelly fine sandy loam; weak medium and coarse subangular blocky structure; friable, moderately smeary; few fine roots; 15 percent subrounded gravel and 5 percent subrounded cobbles; very strongly acid; clear wavy boundary. (Combined thickness of the Bhs horizons is 10 to 24 inches.)

BC—28 to 33 inches; brown (10YR 4/3) gravelly sandy loam; massive with medium and thick plate-like divisions; firm; 20 percent subrounded gravels and 2 percent subrounded cobbles; few fine distinct gray (7.5YR 5/1) areas of iron depletions, and common fine and medium prominent dark red (2.5YR 3/6) soft masses of iron accumulation in the lower part; strongly acid; clear wavy boundary (0 to 10 inches thick).

Cd—33 to 72 inches; olive brown (2.5Y 4/3) gravelly loamy sand; massive with medium and thick plate-like divisions; very firm and brittle; 21 percent subrounded gravels

and 1 percent subrounded cobbles; common medium and coarse prominent dark reddish brown (2.5YR 3/4) soft masses of iron accumulation on some plate like division surfaces in upper part; strongly acid.

The thickness of the solum and depth to densic materials ranges from 20 to 39 inches from the mineral surface. Rock fragment content ranges from 5 to 35 percent by volume in the mineral solum, and 5 to 50 percent in substratum. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil and substratum.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. It is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) material. This horizon has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The A horizon (where present), has hue of 7.5YR to 2.5Y, value of 2 or 3, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or coarse sandy loam in the fine-earth fraction. It has weak or moderate, fine or medium granular structure. Consistence is very friable or friable.

The E horizon has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand or loamy sand in the fine-earth fraction. It has weak fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The Bhs horizons and Bh horizons (where present), have hue of 10R to 7.5YR, with value and chroma of 3 or less. The Bhs and Bh horizons are loam, fine sandy loam, sandy loam, and coarse sandy loam. Ortstein is present in less than 50 percent of some horizons. They have weak or moderate, fine, medium, or coarse granular or subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm. Consistence is moderately or strongly smeary.

The Bs (where present) horizon has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm.

The BC horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. It is massive with or without medium or thick plate-like divisions, or it has weak, medium or coarse subangular blocky structure. Consistence is friable or firm.

The Cd horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is loamy sand, sand, loamy coarse sand, coarse sand, or coarse sandy loam in the fine earth fraction. It is massive with or without medium or thick plate like divisions. Consistence is firm or very firm and brittle.

Factoryville Series

The Factoryville series consists of very deep, well drained soils on deltas, kame terraces, and beach ridges in the Champlain Valley. Factoryville soils formed in stratified, water deposited, sandy sediments. Slopes range from 2 to 60 percent.

Factoryville soils are associated on the landscape with Colonie-calcareous substratum, Windsor, Deerfield, Dunkirk, Niagara, Hartland, Howard soils. Colonie-calcareous substratum and Windsor soils have less than 50 percent fine sand in the profile. Deerfield soils are moderately well drained. Dunkirk is a silty clay soil. Niagara is a silty clay soil and is somewhat poorly drained. Hartland soils are silty. Howard soils are gravelly and are excessively drained (fig. 38).

Typical pedon of Factoryville loamy fine sand, in a map unit of Factoryville-Colonie complex, 3 to 8 percent slopes, in the town of Crown Point, 200 feet southeast of a

Figure 38.—Soil profile of the Factoryville series from a hand dug pit, in the town of Crown Point, in a hay field. Loamy fine sands characterize this soil, and if surface organic matter content can be built up as in this profile, these can be excellent agricultural soils.

point on Vineyard Road, that is .25 miles east of the junction of Vineyard Road and Pearl Street, in a corn field; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1983; lat. 43 degrees 56 minutes 10.2 seconds N. and long. 73 degrees 27 minutes 38.3 seconds W.

Ap—0 to 11 inches, dark brown (10YR 3/3) loamy fine sand; pale brown (10YR 6/3) dry; weak medium and coarse subangular blocky structure parting to weak fine and medium granular structure; very friable; many very fine and common fine roots; 1 percent rock fragments; moderately acid; abrupt smooth boundary.

Bw1—11 to 19 inches, yellowish brown (10YR 5/6) loamy fine sand; single grain; loose; common very fine roots; 1 percent rock fragments; slightly acid; clear smooth boundary.

Bw2—19 to 29 inches, yellowish brown (10YR 5/4) loamy fine sand; single grain; loose; few very fine roots; 3 percent rock fragments; slightly acid; clear wavy boundary.

Bw3—29 to 33 inches, yellowish brown (10YR 5/4) loamy fine sand; single grain; loose; few very fine roots; very few thin clay films bridging sand grains; 1 percent rock fragments; common medium and fine faint brown (7.5YR 4/4) and common medium and fine distinct strong brown (7.5YR 4/6) soft masses of iron accumulation; slightly acid; abrupt wavy boundary.

C1—33 to 65 inches, brown (10YR 4/3) fine sand; single grain; loose; 1 percent rock fragments; neutral; gradual smooth boundary.

C2—65 to 72 inches, brown (10YR 5/3) fine sand; single grain; loose; 1 percent rock fragments; few medium faint dark yellowish brown (10YR 4/4) soft masses of iron accumulation; neutral.

The thickness of the solum ranges from 18 to 40 inches. Texture is dominantly fine sand but may range to sand in some pedons. Pebble content ranges from

0 to 3 percent. Some pedons have carbonates below 40 inches. Redoximorphic concentrations are present in most pedons below 25 inches. Silty or clayey lacustrine layers are present in some pedons below 40 inches.

The Ap horizon has hue of 10YR, value of 3 or 4, and chroma of 1 to 4. The value dry is 6 or more. Uncultivated areas have a thin, 1 to 4 inch thick, A horizon. The A horizons have hue of 10YR, value of 2 or 3, and chroma of 1 or 2. Structure is weak granular or subangular blocky. Texture is fine sand, sand, loamy fine sand, or loamy sand. Reaction ranges from moderately acid to neutral.

Some pedons have a thin E horizon.

The Bw horizon has hue of 10YR or 2.5Y, value of 3 to 7, and chroma of 3 to 8. Texture is fine sand, sand, loamy fine sand, or loamy sand. Structure is weak subangular blocky or single grain, with weak granular in some pedons. Reaction is commonly moderately acid to neutral, but some pedons are strongly acid.

The BC horizon has hue of 10YR or 2.5Y, value of 3 to 7, and chroma of 2 to 6. Structure is massive or single grain, with weak subangular blocky in some pedons. Reaction ranges from moderately acid to neutral.

The C horizon has hue of 10YR or 2.5Y, value of 3 to 7, and chroma of 1 to 6. Texture is fine sand, loamy fine sand, sand, or loamy sand. Structure is massive or single grain. Reaction ranges from moderately acid to neutral.

Farmington Series

The Farmington series consists of shallow, well drained soils on summits, shoulders, and backslopes of scarps, structural benches, and hills in the Champlain Valley. Farmington soils formed in loamy sediments deposited by glacial ice, and are underlain by limestone bedrock. Slopes range from 3 to 60 percent.

Farmington soils are associated on the landscape with Galway, Vergennes, Kingsbury, Niagara, Claverack, Amenia and Windsor soils. Galway soils are 20 to 40 inches deep to limestone bedrock. Vergennes and Kingsbury soils are very deep, clayey, and are moderately well drained and somewhat poorly drained respectively. Niagara soils are very deep, silty clay, and somewhat poorly drained. Claverack soils are very deep, sandy over clayey, and moderately well drained. Amenia soils are very deep, loamy, and moderately well drained. Windsor soils are very deep, sandy, and excessively drained.

Typical pedon of Farmington loam, in a map unit of Farmington-Galway complex, 3 to 15 percent slopes, very rocky, very stony, in a woodlot, in the town of Essex, approximately 300 feet due north of School Road, and 425 feet west-northwest of the water tower; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 18 minutes 24 seconds N. and long. 73 degrees 21 minutes 24 seconds W.

Ap—0 to 6 inches, dark brown (7.5YR 3/2) loam; pale brown (10YR 6/3 dry); weak fine granular structure; very friable; many fine and very fine, common medium and few coarse roots; 10 percent rock fragments; strongly acid; clear smooth boundary.

Bw—6 to 13 inches, brown (7.5YR 4/4) gravelly loam; weak fine and medium subangular blocky structure; very friable; many fine, common medium and very fine, and few coarse roots; 17 percent rock fragments; slightly acid; abrupt smooth boundary.

2R—13 inches, gray massive limestone.

The thickness of the solum and depth to bedrock range from 10 to 20 inches. Rock fragments range from 5 to 35 percent by volume in the solum. Clay content ranges from 10 to 27 percent. The soil reaction ranges from strongly acid to neutral in the A horizon and from moderately acid to slightly alkaline in the B horizon. Free carbonates are in the fine-earth fraction above bedrock in some pedons.

The Ap horizon has hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 1 to 3. Dry color value is 6 or more. Texture is fine sandy loam, loam, or silt loam in the fine-earth fraction. Some pedons may have an A horizon.

The B horizons have hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 6. The color can be mottled with litho chromic ghosts related to the underlying bedrock. Texture is fine sandy loam, very fine sandy loam, loam, or silt loam in the fine earth fraction. Some pedons have redoximorphic accumulations in the lower part of the B horizon. This horizon has weak or moderate, fine or medium subangular blocky or granular structure. Consistence is very friable or friable.

The 2R horizon is dominantly limestone, dolomite, or dolomitic limestone bedrock, but hard shale or sandstone underlies some pedons.

Fernlake Series

The Fernlake series consists of very deep, somewhat excessively drained soils on summits, shoulders, backslopes, and footslopes of glaciated hills and ridges, and on till plains in the Adirondack Upland. Fernlake soils formed in sandy, friable sediments deposited by glacial ice. Slopes range from 3 to 60 percent.

Fernlake soils are associated on the landscape with Adams, Tunbridge, Lyman, Mondadnock, Sunapee, Adirondack, and Tahawus soils. Adams soils have less rock fragments. Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep to meta-igneous bedrock. Lyman soils are loamy, well drained, and are 10 to 20 inches deep to meta-igneous bedrock. Monadnock soils are loamy over sandy or gravelly and are well drained. Sunapee soils are loamy are moderately well drained. Adirondack soils are loamy are somewhat poorly drained. Tahawus soils are very poorly drained (fig. 39).

Typical pedon of Fernlake loamy fine sand, 3 to 8 percent slopes, very bouldery, in a wooded area, in the town of Jay, in a road cut on the east side of Ausable Drive, at a right angle bend, 0.15 mile east of Ridgetop Road; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 26 minutes, 0 seconds N. and long. 73 degrees, 42 minutes, 8 seconds W.

Oa—0 to 2 inches, black (5YR 2.5/1) highly decomposed litter; weak fine granular structure; very friable; many very fine roots; strongly acid; abrupt wavy boundary.

E—2 to 4 inches, brown (7.5YR 5/2) loamy fine sand; weak fine granular structure; very friable; many fine and very fine roots; 10 percent gravel, 2 percent cobbles; very strongly acid; clear wavy boundary.

Bs—4 to 8 inches, brown (7.5YR 4/4) loamy fine sand; weak medium subangular blocky structure; very friable; common fine and medium roots, few coarse roots; 10 percent gravel, 3 percent cobbles; strongly acid; clear smooth boundary.

BC1—8 to 19 inches, yellowish brown (10YR 5/6) gravelly loamy fine sand; weak medium subangular blocky structure; very friable; many fine and very fine roots, few medium and coarse roots; 15 percent gravel, 3 percent cobbles; very strongly acid; clear smooth boundary.

BC2—19 to 33 inches, brown (10YR 5/3) gravelly loamy fine sand; weak medium subangular blocky structure; very friable; common fine and very fine roots; 10 percent gravel, 5 percent cobbles; very strongly acid; clear wavy boundary.

C1—33 to 41 inches, pale brown (10YR 6/3) gravelly loamy sand; massive with weak very thick and thin plate-like divisions; friable; few fine roots; 10 percent gravel, 5 percent cobbles; strongly acid; clear wavy boundary.

C2—41 to 57 inches, brown (10YR 5/3) cobbly loamy sand; massive; very friable; few fine roots in upper part; 10 percent cobbles, 10 percent gravel; strongly acid; clear wavy boundary.

C3—57 to 72 inches, mixed 50 percent brown (10YR 5/3) and 30 percent very pale brown (10YR 7/3) sand; a few thin lenses of brown (10YR 5/3) fine sand; single grain; loose; 10 percent gravel; strongly acid.

The thickness of the solum ranges from 15 to 40 inches. Depth to bedrock is greater than 60 inches. Rock fragments range from 5 to 30 percent in the solum and from 10 to 40 percent in the substratum. Reaction is extremely acid to strongly acid in the upper part of the solum, very strongly acid to moderately acid in the BC horizon, and strongly acid to slightly acid in the substratum.

Some pedons have thin Oe and/or Oa horizons.

The A horizon has hue of 5YR or 7.5YR, value of 2 to 3, and chroma of 1 or 2. Texture of the fine earth fraction is dominantly loamy sand, but includes loamy fine sand and sandy loam. Structure is weak granular. Consistence is friable or very friable.

The E horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 1 to 3. Texture of the fine earth fraction is dominantly loamy sand, but includes loamy fine sand and fine sand. Structure is weak granular or the horizon is single grain. Consistence is friable or very friable.

The Bs horizon has hue of 5YR to 10YR, value of 4 or 5, and chroma of 3 to 6. Texture of the fine earth fraction is dominantly loamy sand, however thin subhorizons of loamy fine sand or sandy loam are in some pedons. Structure is weak, fine to coarse granular or subangular blocky. Consistence is friable or very friable.

The BC horizon has hue of 7.5YR or 10YR, value of 4 to 6, and chroma of 2 to 6. Texture of the fine earth fraction is dominantly loamy sand, but also includes loamy fine sand, sand, or fine sand. Structure is weak, fine or medium subangular blocky, or the horizon is single grain.

The C horizon has hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 2 or 3. Texture of the fine earth fraction is dominantly loamy sand, but also includes loamy fine sand, sand, or fine sand. Some pedons have thin subhorizons of sandy loam below 40 inches. The horizon is massive or single grain. Some pedons have thin layers below 40 inches (being less than 20 inches total thickness), of weak platy structure. Consistence is friable to loose, and may be firm in place.

Figure 39.—Soil profile of the Fernlake series from a borrow pit, in the town of Jay, in a mixed pine and hardwood forest. Note the bright reddish brown spodic subsoil horizon underlying the gray albic horizon. These sandy tills have excellent potential for production of drier site timber species such as Pine, Oak, and Cherry. This soil also has moderate limitations for residential development.

Fluvaquents

Fluvaquents consist of very deep, somewhat poorly drained to very poorly drained soils formed in material recently deposited by streams and rivers. Fluvaquents are on the most actively flooded areas of flood plains along major and secondary streams in the county. Slopes range from 0 to 3 percent. Fluvaquents are in areas of the flood plain immediately adjacent to streams. Scouring, cutting, lateral erosion, changing stream channels and redeposition of sediments during frequent flooding are responsible for the variability in composition and properties of Fluvaquents.

Fluvaquents occur in a complex with the well drained Udifluvents soils, and are mapped in both the frigid and mesic areas of the county. They are commonly near Ondawa, Occum, Podunk, Pootatuck, Lovewell, Cornish, Rumney, Rippowam, Charles, Medomak, and Burnt Vly soils. The frigid Ondawa and mesic Occum soils are well drained. The frigid Podunk and mesic Pootatuck soils are moderately well drained. The frigid Rumney and mesic Rippowam soils are poorly drained. The frigid Burnt Vly soils are organic over sandy and are very poorly drained. The frigid and moderately well drained Lovewell, somewhat poorly drained Cornish, poorly drained Charles, and very poorly drained Medomak soils are silty. Fluvaquents have little or no soil profile development.

Although these soils are highly variable, an example of the loamy phase is provided here: Pedon of Fluvaquents, in a map unit of Fluvaquents-Udifluvents complex, frequently flooded, nearly level, in a wooded area, town of Elizabethtown, Elizabethtown Fish & Game Club Property, 1,535 feet north and slightly east of the junction of the club road and the Elizabethtown-Wadhams road; USGS Elizabethtown, NY 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees 13 minutes 54.9 seconds N. and long. 73 degrees 34 minutes 11.3 seconds W.

A—0 to 5 inches, very dark brown (10YR 2/2) very fine sandy loam; weak fine and medium granular structure; very friable; many fine and very fine roots; slightly acid; clear smooth boundary.

AC—5 to 9 inches, 70 percent very dark grayish brown (10YR 3/2) and 30 percent light olive brown (2.5Y 5/3) fine sandy loam; weak fine granular structure; very friable; many fine and very fine roots; slightly acid; clear smooth boundary.

Ab—9 to 21 inches, very dark grayish brown (10YR 3/2) very fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and few medium roots; few fine distinct gray (2.5Y 5/1) depletions, and few fine prominent yellowish brown (10YR 5/8) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Cg1—21 to 30 inches, dark gray (10YR 4/1) very fine sandy loam; massive; friable; few fine and medium roots; many fine and medium prominent dark reddish brown (5YR 3/4) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Cg2—30 to 42 inches, dark gray (2.5Y 4/1) fine sandy loam; massive; friable; few fine roots; slightly acid; clear smooth boundary.

2Cg3—42 to 72 inches, dark gray (10YR 4/1) very gravelly sand; single grain; loose; 50 percent gravels; neutral.

Generally the surface layer is 3 to 15 inches thick. The depth to bedrock is more than 60 inches.

The surface layer or buried A horizons have hue of 10YR to 5Y or is neutral, value of 2 to 5, and chroma of 1 to 6. Texture is very fine sandy loam to coarse sand, and their gravelly or very gravelly analogs. Rock fragments range from 0 to 70 percent. Reaction is strongly acid to neutral.

The substratum has hue of 10YR to 5PB, value of 3 to 5, and chroma of 1 to 6. Redoximorphic features in the form of iron depletions are present above 20 inches. Texture is very fine sandy loam through coarse sand, and their gravelly or very gravelly

analogs. Structure is massive or single grain. Rock fragments range from 0 to 70 percent. Reaction is strongly acid to neutral.

Correlation Note: Included in the FuA map unit are some areas of frigid soils. This should not affect use and management of this map unit.

Galway Series

The Galway series consists of moderately deep, well drained soils on summits and shoulders of structural benches and hills in the Champlain Valley. Galway soils formed in loamy sediments deposited by glacial ice, and underlain by limestone bedrock. Slopes range from 3 to 15 percent.

Galway soils are associated on the landscape with Farmington, Vergennes, Kingsbury, Niagara, Claverack, Amenia and Windsor soils. Farmington soils are 10 to 20 inches deep to limestone bedrock. Vergennes and Kingsbury soils are very deep, clayey, and are moderately well drained and somewhat poorly drained respectively. Niagara soils are very deep, silty clay, and somewhat poorly drained. Claverack soils are very deep, sandy over clayey, and moderately well drained. Amenia soils are very deep, loamy, and moderately well drained. Windsor soils are very deep, sandy, and excessively drained.

Typical pedon of Galway loam, in a map unit of Farmington-Galway complex, 3 to 15 percent slopes, very rocky, very stony, in the town of Essex, in the hamlet of Essex, 2,200 feet south of the junction of NYS Route 22 and County Route 22J, 300 feet north-east of County Route 22J; USGS Willsboro, NY 15 minute quadrangle; NAD 1927; lat. 44 degrees 18 minutes 16 seconds N. and long. 73 degrees 20 seconds 58 minutes W.

Ap—0 to 5 inches, very dark grayish brown (10YR 3/2) loam; light brownish gray (10YR 6/2) dry; moderate fine and medium granular structure; friable; many fine, and common medium and coarse roots; 5 percent rock fragments; neutral; abrupt smooth boundary.

Bw1—5 to 9 inches, dark brown (10YR 3/3) fine sandy loam; moderate fine and medium granular structure; friable; common fine and medium, and few coarse roots; common fine tubular pores; 7 percent rock fragments; neutral; gradual smooth boundary.

Bw2—9 to 18 inches, brown (10YR 4/3) fine sandy loam; moderate fine and medium subangular blocky structure; friable; common fine and medium, and few coarse roots; common fine tubular and few fine vesicular pores; 7 percent rock fragments; neutral; clear smooth boundary.

C—18 to 35 inches, grayish brown (2.5Y 5/2) gravelly fine sandy loam; common medium prominent white (10YR 8/1) soft masses of secondary calcium carbonate accumulation; massive with moderate thin and medium plate-like divisions; firm; few fine tubular pores; 25 percent rock fragments; moderately alkaline, violent effervescent; abrupt smooth boundary.

2R—35 inches, nearly horizontally bedded limestone bedrock.

The thickness of solum ranges from 18 to 30 inches and depth to carbonates ranges from 14 to 40 inches. Depth to bedrock ranges from 20 to 40 inches. Rock fragments, by volume, range from 0 to 35 percent in the A horizon, 3 to 35 percent in the B horizon, and 5 to 70 percent in the C horizon. The soil is moderately acid to neutral in the A horizon, moderately acid to slightly alkaline in the B horizon, and slightly or moderately alkaline in the C horizon.

The Ap or A horizon has hue of 10YR or 2.5Y, value of 3 or 4 and chroma of 2 or 3. Texture is silt loam or loam in the fine earth fraction. The structure is fine to coarse granular or fine or medium subangular blocky. The consistence is very friable or friable. The A horizon has a thickness of 2 to 5 inches.

The Bw horizon has hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 3 to 6. Faint or distinct mottles or redoximorphic concentrations with chroma higher than 2 occur in the lower part of some pedons. Texture of the fine earth fraction is silt loam, loam, or fine sandy loam. It has weak or moderate, fine through coarse, subangular blocky or granular structure. Consistence ranges from very friable to firm.

BC horizon, if present, is similar to the Bw but differs by having free carbonates and chroma as low as 2.

The C horizon has hue of 5YR to 2.5Y, value of 3 to 6 and chroma of 2 to 4. If chroma is 2, the value is 4 or more. Texture ranges from silt loam to sandy loam in the fine earth fraction. Texture is friable or firm. It is calcareous in some part.

The 2R horizon is limestone, dolomitic limestone, or calcareous sandstone bedrock.

Georgia Series

The Georgia series consists of very deep, moderately well drained soils on till plains and on footslopes of glaciated hills and ridges in the Champlain Valley. Georgia soils formed in loamy, friable sediments deposited by glacial ice. Slopes range from 3 to 15 percent.

Georgia soils are associated on the landscape with Pittsfield, Massena, Sun, Chatfield, Hollis and Kingsbury soils. Pittsfield soils are well drained. Massena soils are somewhat poorly drained. Sun soils are poorly drained. Chatfield and Hollis soils are well drained and are 20 to 40 inches and 10 to 20 inches deep to meta-igneous bedrock respectively. Kingsbury soils are clayey and are somewhat poorly drained.

Typical pedon of Georgia loam, 3 to 8 percent slopes, in the town of Essex, 250 feet south of a point on County Route 12, that is 3,450 feet east of the junction of County Route 12 and Spear Road, in a wood lot; USGS Willsboro, NY 15 minute quadrangle; NAD 1927; lat. 44 degrees 18 minutes 22 seconds N. and long. 73 degrees 26 minutes 49 seconds W.

A—0 to 9 inches, very dark grayish brown (10YR 3/2) loam; light brownish gray (10YR 6/2) dry; moderate medium granular structure; very friable; many fine and very fine roots and few coarse roots; 10 percent rock fragments; slightly acid; clear wavy boundary.

Bw1—9 to 15 inches, brown (10YR 4/3) loam; weak medium subangular blocky structure; very friable; common fine and very fine roots and few medium roots; 11 percent rock fragments; few medium faint pale brown (10YR 6/3) and few medium distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation; moderately acid; clear smooth boundary.

Bw2—15 to 20 inches, dark yellowish brown (10YR 4/4) fine sandy loam; moderate medium subangular blocky structure; friable; few fine and very fine roots; 9 percent rock fragments; common fine faint pale brown (10YR 6/3) and common fine distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation; moderately acid; clear smooth boundary.

BC—20 to 30 inches, light olive brown (2.5Y 5/4) fine sandy loam; weak medium subangular blocky structure; friable; 13 percent rock fragments; few fine distinct grayish brown (10YR 5/2) iron depletions, many medium and fine distinct dark yellowish brown (10YR 4/6) and common medium faint brown (10YR 5/3) soft masses of iron accumulation; moderately acid; clear smooth boundary.

C—30 to 72 inches, light olive brown (2.5Y 5/4) gravelly fine sandy loam; massive; friable; 23 percent rock fragments; common medium distinct light brownish gray (2.5Y 6/2) iron depletions, common medium distinct yellowish brown (10YR 5/6) and dark yellowish brown (10YR 4/4) soft masses of iron accumulation; moderately acid.

The thickness of the solum ranges from 16 to 32 inches. Depth to bedrock is more than 60 inches. Rock fragments range from 0 to 55 percent in individual horizons and the weighted average in the control section ranges from 5 to 35 percent. Rock fragments consist mainly of weathered limestone, shale, and slate with small amounts of granite. Reaction typically ranges from strongly acid to neutral, but ranges to slightly alkaline in the lower solum and substratum of some pedons. Depth to free carbonates is greater than 40 inches.

The A horizon has hue of 10YR or 2.5Y, value of 3 or 4, and chroma of 2 or 3. Texture is loam, or silt loam in the fine-earth fraction.

Some pedons have a BA horizon up to 4 inches thick, with hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 3 to 6. Texture is fine sandy loam, loam, or silt loam in the fine-earth fraction

The Bw horizon has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 3 to 6. Texture is fine sandy loam, loam, or silt loam in the fine-earth fraction.

Some pedons have a BC horizon with hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 to 4. Texture is fine sandy loam, loam, or silt loam in the fine-earth fraction.

The C horizon is neutral or has hue of 10YR to 5Y, value of 3 to 5, and chroma of 1 to 4. Texture is fine sandy loam, loam, or silt loam in the fine-earth fraction.

Gougeville Series

The Gougeville series consists of very deep, poorly drained soils in nearly level areas on delta perimeters and lake plains. Gougeville soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 3 percent.

Gougeville soils are associated on the landscape with Stafford, Cosad, Whallonsburg, and Sun soils. Stafford soils are somewhat poorly drained. Cosad soils have a sandy subsoil over a clay substratum at depths of 20 to 40 inches, and are somewhat poorly drained. Whallonsburg soils are very poorly drained organic soils over clay. Sun soils are loamy.

Typical pedon of Gougeville mucky loamy fine sand, in the town of Plattsburgh, Clinton County NY, about 2,400 feet east of State Route 22 and about 400 feet south of South Junction Road, in a brushy meadow; USGS Plattsburgh, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 44 degrees 37 minutes 59 seconds N. and long. 73 degrees 28 minutes 47 seconds W.

A—0 to 6 inches, very dark brown (10YR 2/2) mucky loamy fine sand; dark grayish brown (10YR 4/2) dry; weak fine granular structure; very friable; many very fine roots and common fine and medium roots; moderately acid; clear smooth boundary.

C1—6 to 12 inches, light brownish gray (10YR 6/2) fine sand; single grain; loose; common very fine roots and few fine roots; many medium and coarse prominent strong brown (7.5YR 4/6) soft masses of iron accumulation (some slightly firm ortstein), common black (N 2/0) stains of manganese oxides, few yellowish brown (10YR 5/6) iron stains along root channels; moderately acid; abrupt smooth boundary.

C2—12 to 25 inches, grayish brown (10YR 5/2) fine sand; single grain; very friable; few very fine roots; many coarse and medium prominent dark yellowish brown (10YR 4/6) and strong brown (7.5YR 4/6) soft masses of iron accumulation, common coarse faint gray (10YR 6/1) iron depletions; moderately acid; gradual smooth boundary.

C3—25 to 40 inches, grayish brown (10YR 5/2) fine sand; single grain; very friable; common coarse and medium prominent yellowish brown (10YR 5/6) and common coarse distinct yellowish brown (10YR 5/4) soft masses of iron accumulation, common coarse and medium faint gray (10YR 6/1) iron depletions; moderately acid; clear smooth boundary.

C4—40 to 58 inches, gray (10YR 5/1) fine sand; single grain; very friable; common coarse prominent light olive brown (2.5Y 5/4) soft masses of iron accumulation; slightly acid; clear smooth boundary.
C5—58 to 72 inches, dark gray (N 4/0) fine sand; single grain; loose; slightly alkaline.

The thickness of the solum ranges from 6 to 25 inches. Depth to bedrock is greater than 60 inches. Rock fragments are typically absent, but may range up to 2 percent by volume in the substratum. Redoximorphic features consisting of Fe/Mn concentrations or clay depletions occur above 20 inches.

The Ap horizon has hue of 10YR, value of 2 or 3 and chroma of 1 or 2. Texture is fine sand, loamy fine sand or fine sandy loam with or without mucky analogues. Some pedons in uncultivated areas have an A horizon with value or chroma one unit lower than an Ap horizon. Reaction ranges from strongly acid to slightly acid.

Some pedons have a Bg horizon with hue of 10YR to 5Y, or neutral, value of 4 to 6, and chroma of 0 to 2. Texture is fine sand or loamy fine sand. Structure is weak subangular blocky or granular. Consistence is very friable. Reaction ranges from moderately acid to slightly alkaline.

The C horizon has hue of 10YR to 5Y, or is neutral, value of 3 to 6, and chroma of 0 to 2. Texture above a depth of 40 inches is fine sand or loamy fine sand. Below 40 inches, some pedons have thin subhorizons of loamy very fine sand, very fine sandy loam and silt loam. The Cg horizon is generally single grain or massive. Consistence is friable, very friable or loose. Reaction ranges from moderately acid to slightly alkaline.

Hailesboro Series

The Hailesboro series consists of very deep, somewhat poorly drained soils on lacustrine terraces in intermontane valleys of the Adirondack Upland. Hailesboro soils formed in silty clay sediments deposited in still water. Slopes range from 3 to 8 percent.

Hailesboro soils are associated on the landscape with Champlain, Depeyster, Becket, Tunbridge, Roundabout, and Wegatchie soils. Champlain soils are sandy and are excessively drained to somewhat excessively drained. Depeyster soils are moderately well drained. Becket soils are loamy and are well drained. Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep to meta-igneous bedrock. Roundabout soils are silty. Wegatchie soils are poorly drained.

Typical Pedon of Hailesboro very fine sandy loam, 3 to 8 percent slopes, in a white pine plantation, town of Jay, 2,200 feet south from intersection of North Jay Road and Hazen Road, then 600 feet west from edge of field into plantation; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 23 minutes 32 seconds N. and long. 73 degrees 40 minutes 33 seconds W.

Oi—0 to 1 inch, slightly decomposed needle and twig material.
Ap—1 to 9 inches, very dark grayish brown (10YR 3/2) very fine sandy loam; light brownish gray (10YR 6/2) dry; weak fine granular structure; very friable; many fine and very fine, common medium, and few coarse roots; slightly acid; abrupt smooth boundary.
BE—9 to 17 inches, brown (10YR 5/3) very fine sandy loam; weak fine subangular blocky structure; very friable; common fine and very fine roots; few fine tubular pores; many medium distinct yellowish brown (10YR 5/6) and common fine prominent strong brown (7.5YR 5/6) masses of iron accumulation, and common fine and medium distinct gray (10YR 6/1) iron depletions; slightly acid; clear wavy boundary.
Beg—17 to 23 inches, light brownish gray (2.5Y 6/2) very fine sandy loam; weak medium subangular blocky structure; very friable; few very fine roots; common fine tubular pores; common medium prominent yellowish brown (10YR 5/6) masses of iron accumulation, and common medium faint gray (2.5Y 6/1) iron depletions; slightly acid; abrupt wavy boundary.

Bt1—23 to 30 inches, grayish brown (10YR 5/2) silt loam; moderate medium and coarse subangular blocky structure; firm; few distinct clay films on ped faces and pore linings; common fine and medium tubular and few medium vesicular pores; many coarse faint brown (7.5YR 5/3) and common fine prominent strong brown (7.5YR 5/6) masses of iron accumulation, and common medium faint gray (10YR 6/1) iron depletions; neutral; gradual wavy boundary.

Bt2—30 to 44 inches, grayish brown (10YR 5/2) silty clay loam; weak medium and coarse subangular blocky structure; firm; common distinct clay films on ped faces and pore linings; common fine and medium tubular and few medium vesicular pores; many coarse faint brown (7.5YR 5/3) and common fine prominent strong brown (7.5YR 5/6) masses of iron accumulation, and common medium faint gray (10YR 6/1) iron depletions; neutral; gradual wavy boundary.

C1—44 to 54 inches, grayish brown (2.5Y 5/2) silt loam; weak thin platy structure; friable; common fine tubular pores; common coarse distinct brown (7.5YR 5/3) and few fine prominent yellowish brown (10YR 5/6) masses of iron accumulation, and common medium faint gray (2.5Y 6/1) iron depletions; neutral; gradual wavy boundary.

C2—54 to 72 inches, grayish brown (2.5Y 5/2) very fine sandy loam; massive; friable; common fine tubular pores; few coarse distinct brown (7.5YR 5/3) masses of iron accumulation and few medium faint gray (2.5Y 6/1) iron depletions; slightly alkaline.

The thickness of the solum ranges from 22 to 45 inches. Depth to carbonates range from 30 to 80 inches. Redoximorphic features occur within 20 inches of the mineral soil surface. Depth to bedrock is greater than 60 inches. Rock fragments range from 0 to 5 percent by volume throughout the soil.

The Ap or A horizon has hue of 10YR or 2.5Y, value of 3 or 4, and chroma of 1 to 3. Texture is silt loam or very fine sandy loam in the fine earth fraction. Reaction ranges from moderately acid to neutral.

The BE or BEg horizon, where present, has hue of 10YR or 2.5Y, value of 5 or 6, and chroma of 1 to 3. Texture is silt loam or very fine sandy loam in the fine earth fraction. Reaction ranges from moderately acid to slightly alkaline.

The Btg or Bt horizon has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 1 or 2. Texture is dominantly silt loam or silty clay loam in the fine earth fraction, with thin subhorizons of very fine sandy loam. Reaction ranges from moderately acid to slightly alkaline.

The BCg or BC horizon, where present, has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 1 to 3. Texture is very fine sandy loam, silt loam or silty clay loam in the fine earth fraction. Reaction ranges from neutral to moderately alkaline.

The Cg or C horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 1 to 3. Texture is very fine sandy loam, silt loam, silty clay loam, or silty clay in the fine earth fraction. Reaction is ranges from neutral to moderately alkaline.

Haplosaprists

Haplosaprists soils consist of very deep, very poorly drained mucky soils in depressions on deltas, outwash plains and outwash terraces in the Adirondack Upland. Haplosaprists soils formed in saturated, decomposing plant material overlying sandy sediments. Slope ranges from 0 to 3 percent.

Haplosaprists soils are associated on the landscape with Searsport, Naumburg, Croghan, Rumney, and Monadnock soils. Searsport soils are sandy throughout. Naumburg soils are sandy throughout and are somewhat poorly drained. Croghan soils are sandy throughout and are moderately well drained. Rumney soils are loamy and are poorly drained. Monadnock soils are loamy over sandy or gravelly, and are well drained.

Typical pedon of Haplosaprists, in a map unit of Searsport-Haplosaprists-Naumburg complex, 0 to 3 percent slopes, in a wooded area, town of North Elba, 1,000 feet south on old Penn Central rail line from Route 86, then 200 feet east into woods; USGS Saranac Lake 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees 18 minutes 07 seconds N. and long. 74 degrees 06 minutes 36 seconds W.

Oa1—0 to 10 inches, very dark brown (10YR 2/2) broken face and rubbed muck (sapric material); 25 percent unrubbed fiber, 5 percent rubbed fiber; weak fine and medium granular structure; very friable; common very fine roots; extremely acid; clear smooth boundary.

Oa2—10 to 20 inches, black (10YR 2/1) broken face and rubbed muck (sapric material); 12 percent unrubbed fiber, less than 1 percent rubbed fiber; weak fine and medium subangular blocky structure; very friable; few very fine roots; extremely acid; clear smooth boundary.

2Cg—20 to 72 inches; gray (5Y 5/1) loamy fine sand; massive; very friable; slightly acid.

The depth to the mineral horizon ranges from 16 to 51 inches. The organic part of the control section has a pH of less than 4.5 in 0.01M calcium chloride.

The surface and subsurface tiers have hue of 10YR to 5YR, or is neutral, value of 2 to 6, and chroma of 0 to 3. The materials are dominantly muck (sapric material), but layers of peat (fibric material) totaling less than 5 inches in thickness and mucky peat (hemic material) totaling less than 10 inches are in some pedons. They are typically massive with some pedons having weak platy, blocky, or granular structure

The 2Cg horizon is neutral or has hue of 10YR to 5Y, value of 4 to 6, and chroma of 0 to 4. Redoximorphic features are faint to prominent, few to many, and fine to coarse, or may be absent. The C horizon is loamy fine sand, loamy sand, fine sand, sand or coarse sand in the fine-earth fraction and some pedons are stratified. Reaction is very strongly acid to slightly acid. Gravel, by volume, ranges from 0 to 45 percent.

Hartland Series

The Hartland series consists of very deep, well drained soils on deltas, lacustrine terraces, and lake plains in the Champlain Valley. Hartland soils formed in water deposited, stratified silt and very fine sand sediments. Slopes range from 2 to 8 percent.

Hartland soils are associated on the landscape with Factoryville, Dunkirk, Vergennes, Kingsbury, Farmington, and Howard soils. Factoryville soils are sandy. Dunkirk soils have higher clay contents. Vergennes and Kingsbury soils are clayey and are moderately well drained and somewhat poorly drained respectively. Farmington soils are loamy, and are 10 to 20 inches deep to limestone bedrock. Howard soils are gravelly and are well drained and somewhat excessively drained.

Typical pedon of Hartland very fine sandy loam, 2 to 8 percent slopes, in an apple orchard, in the town of Crown Point, 300 feet south of a point on Russell Street, that is 5,000 feet west of the junction of Russell Street and Factoryville Road; USGS Crown Point, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 57 minutes 42 seconds N. and long. 73 degrees 27 minutes 42 seconds W.

Ap—0 to 12 inches, dark brown (10YR 3/3) very fine sandy loam; pale brown (10YR 6/3) dry; moderate fine and medium granular structure; very friable; many fine and few medium and coarse roots; slightly acid; abrupt smooth boundary.

Bw1—12 to 19 inches, yellowish brown (10YR 5/4) very fine sandy loam; moderate medium and coarse subangular blocky structure; very friable; common fine and few medium roots; common fine and few medium tubular pores; neutral; clear wavy boundary.

Bw2—19 to 30 inches, brown (10YR 5/3) very fine sandy loam; weak medium and coarse subangular blocky structure; very friable; few fine and medium roots; common fine and few medium tubular pores; neutral; clear smooth boundary.

C1—30 to 45 inches, 60 percent dark yellowish brown (10YR 4/4) and 30 percent yellowish brown (10YR 5/4) silt loam; massive weak medium and thin plate-like divisions; friable; few fine roots; 10 percent pale brown (10YR 6/3) skeletans on plate surfaces; few fine tubular pores; neutral; clear wavy boundary.

C2—45 to 60 inches, yellowish brown (10YR 5/4) very fine sandy loam; massive with weak thick and medium plate-like divisions; very friable; few fine roots; few fine tubular pores; neutral; clear wavy boundary.

C3—60 to 72 inches, 70 percent yellowish brown (10YR 5/4) and 30 percent pale brown (10YR 6/3) fine sandy loam; massive with weak thick and medium plate-like divisions; very friable; many coarse distinct light gray (10YR 7/2) and very pale brown (10YR 7/3) skeletans on plate surfaces; few fine tubular pores; neutral.

The thickness of the solum ranges from 14 to 40 inches. Depth to bedrock is greater than 60 inches. Rock fragments range from 0 to 5 percent. The dominant textures throughout the soil are very fine sandy loam, silt loam, and silt. Fine sandy loam, loamy very fine sand, and very fine sand are allowed in the lower part of the substratum. Thin strata of coarser and finer textured material are common in the lower part of the solum and the substratum of some pedons. Reaction ranges from strongly acid to slightly alkaline.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 or 3. Some pedons have an A horizon. Some pedons have a thin E horizon.

The upper part of the Bw horizon has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 3 to 6. The lower part of the Bw has hue of 10YR to 5Y, value of 4 to 7, and chroma of 2 to 8. Some pedons have a BC horizon.

The C horizon is neutral or has hue of 10YR to 5Y, value of 3 to 6, and chroma of 2 to 6.

Hermon Series

The Hermon series consists of very deep, somewhat excessively drained soils on footslopes of glaciated hills and ridges, and on till plains in the Adirondack Upland. These soils formed in gravelly, friable sediments deposited by glacial ice. Slopes range from 3 to 60 percent.

Hermon soils are associated on the landscape with Colton, Monadnock, Tahawus, Adirondack, Becket, Skerry, and Tunbridge soils. Colton soils are stratified and excessively drained. Monadnock soils are loamy over sandy or gravelly, and are well drained. Tahawus soils are sandy and very poorly drained. Adirondack soils are loamy and somewhat poorly drained. Becket soils are loamy and well drained. Skerry soils are loamy and moderately well drained. Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep to meta-igneous bedrock.

Typical pedon of Hermon gravelly loamy sand, 35 to 60 percent slopes, very bouldery, in the town of Chesterfield, on west-northwest/east-southeast trending ridge between Black Ash Mt. and Hogback Mt., 100 feet southeast of trail where it passes through “Natural Dam”; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 20 minutes 55 seconds N. and long. 73 degrees 38 minutes 49 seconds W.

Oi—0 to 1 inch, slightly decomposed leaf, needle, and twig litter.

Oa—1 to 3 inches, black (10YR 2/1) highly decomposed (sapric) plant material; weak fine granular structure; very friable; many fine and very fine, few medium and coarse roots; 5 percent gravels, 1 percent cobbles, 1 percent stones; extremely acid; abrupt wavy boundary.

E—3 to 5 inches, brown (7.5YR 5/2) gravelly loamy sand; weak fine subangular blocky parting to weak fine and very fine granular structure; very friable; common fine and very fine, few medium roots; 15 percent gravels, 5 percent cobbles, 1 percent stones; very strongly acid; abrupt wavy boundary.

Bhs—5 to 10 inches, dark reddish brown (5YR 3/3) gravelly loamy sand; weak fine and medium granular structure; friable; many fine and very fine, few medium and coarse roots; 20 percent gravels, 5 percent cobbles, 2 percent stones; strongly acid; clear irregular boundary.

Bs—10 to 20 inches, brown (7.5YR 4/4) very gravelly loamy sand; weak fine and medium subangular blocky parting to weak fine granular structure; friable; common fine and very fine, few medium roots; 25 percent gravels, 10 percent cobbles, 3 percent stones; strongly acid; gradual irregular boundary.

C1—20 to 29 inches, dark yellowish brown (10YR 4/4) very gravelly sand; massive parting to weak thin platy structure; friable; few fine and very fine roots; 30 percent gravels, 10 percent cobbles, 5 percent stones; strongly acid; gradual wavy boundary.

C2—29 to 38 inches, brown (10YR 4/3) very gravelly sand; massive; friable; few fine and very fine roots; 35 percent gravels, 10 percent cobbles, 5 percent stones; strongly acid; gradual wavy boundary.

C3—38 to 72 inches, brown (10YR 5/3) very gravelly sand; massive; friable; 35 percent gravels, 10 percent cobbles, 5 percent stones; strongly acid.

The thickness of the solum ranges from 14 to 35 inches. Depth to bedrock is more than 60 inches. Rock fragment content in individual horizons of the particle-size control section ranges from 15 to 70 percent, but the weighted average ranges from 35 to 65 percent. The rock fragments are about 1/3 cobbles and stones and 2/3 gravel. The rock fragment content of the upper 10 inches of the mineral soil ranges from 5 to 50 percent. Stones and boulders cover from 0 to 15 percent of the surface. The surface and subsurface horizons range from extremely acid to strongly acid, the subsoil from extremely acid to moderately acid, and the substratum is strongly acid or moderately acid.

The O horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 3 and chroma of 0 to 2. This horizon has weak very fine or fine granular structure. Consistence is very friable or friable. The horizon has slightly to highly decomposed plant material (sapric, hemic, or fibric).

The Ap horizon, where present, has hue of 10YR, value of 3 or 4 and chroma of 2 or 3. Some pedons have an A horizon that is up to 5 inches thick with hue of 10YR, value of 2 or 3 and chroma of 1 to 3. The A horizon is sandy loam, fine sandy loam, or coarse sandy loam in the fine-earth fraction. It has weak very fine to medium granular structure. Consistence is very friable or friable.

The E horizon has hue of 5YR to 2.5Y, value of 5 to 7, and chroma of 1 or 2. Texture is sandy loam, fine sandy loam, coarse sandy loam, loamy fine sand, or loamy sand in the fine-earth fraction. The horizon has weak very fine to medium granular or subangular blocky structure, or it is weak thin or medium platy. Consistence is very friable or friable.

The Bhs horizon has hue of 2.5YR to 7.5YR, value of 2 to 3 and chroma of 1 to 3. The Bh horizon, where present, has hue of 2.5YR to 7.5YR, value of 2 to 5 and chroma of 2 to 6. The Bs horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 4 to 8. They are fine sandy loam, sandy loam, coarse sandy loam, loamy sand, loamy coarse sand, sand, or coarse sand in the fine-earth fraction. The B horizons have weak to moderate, very fine to medium granular or subangular blocky structure or are single grain or massive where cemented. Consistence ranges from loose to friable but some pedons have discontinuous cementation.

The BC horizon, where present, has hue of 10YR or 2.5Y, value of 4 to 6 and chroma of 3 to 6. Texture is sandy loam, coarse sandy loam, loamy sand, loamy coarse

sand, sand, or coarse sand in the fine-earth fraction. This horizon has weak very fine to medium granular or platy structure or is single grain or massive. Consistence is loose to firm but some pedons have discontinuous cementation.

The C horizon has hue of 10YR to 5Y, value of 4 to 7 and chroma of 1 to 4. Texture is loamy sand, loamy coarse sand, sand, or coarse sand in the fine-earth fraction. It has weak thin or medium platy structure, or it is single grain or massive. Consistence is loose to firm.

Hogback Series

The Hogback series consists of shallow, well drained soils on summits, shoulders, and backslopes of glaciated mountains, hills and ridges in the Adirondack Upland. Hogback soils formed in loamy sediments deposited by glacial ice and are underlain by massive meta-igneous bedrock. Slopes range from 3 to 60 percent.

Hogback soils are associated on the landscape with Knob Lock, Rawsonville, Mundalite, Worden, and Wilmington soils. Knob Lock soils are organic and are 1 to 20 inches deep to meta-igneous bedrock. Rawsonville soils are 20 to 40 inches deep to meta-igneous bedrock. Mundalite soils are very deep. Worden soils are very deep and somewhat poorly drained. Wilmington soils are very deep and poorly drained (fig. 40).

Typical pedon of Hogback fine sandy loamy, in a map unit of Hogback-Knob Lock complex, 35 to 60 percent slopes, very rocky, very bouldery, in a forested area, in the town of Lewis, approximately 300 feet south off summit of small shoulder ridge south-southeast of Spruce Hill; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees 16 minutes 48.7 seconds N. and long. 73 degrees 40 minutes 23.3 seconds W.

Oe—0 to 1 inch, reddish black (2.5YR 2.5/1) moderately decomposed (hemic) plant material; about 50 percent fiber, 15 percent rubbed; weak fine granular structure; very friable; many fine and very fine, and common medium roots; very strongly acid; clear wavy boundary.

Oa—1 to 3 inches, black (N 2.5/) highly decomposed (sapric) plant material; about 20 percent fiber, 5 percent rubbed; weak fine granular structure; very friable; many fine and very fine, and common medium roots; very strongly acid; abrupt wavy boundary.

E—3 to 4 inches, gray (5YR 5/1) fine sandy loam; weak fine granular structure; very friable; many fine and very fine, and common medium roots; 5 percent rock fragments; very strongly acid; clear wavy boundary.

Bhs1—4 to 6 inches, dark reddish brown (5YR 2.5/2) fine sandy loam; weak fine and medium subangular blocky structure; friable, moderately smeary; many fine and very fine, and common medium roots; 5 percent rock fragments; strongly acid; clear wavy boundary.

Bhs2—6 to 14 inches, dark reddish brown (5YR 3/3) fine sandy loam; weak medium subangular blocky structure; friable, weakly smeary; few fine pores; common fine and very fine roots; 5 percent rock fragments; strongly acid; abrupt wavy boundary.

R—14 inches, metaanorthosite bedrock.

The thickness of the solum and depth to bedrock range from 10 to 20 inches. Reaction typically ranges from extremely acid to strongly acid throughout the soil, but some pedons are moderately acid just above the bedrock. Rock fragments are mostly gravel, channers or cobbles and range from 5 to 34 percent throughout the mineral soil. The spodic horizon is 4 to 18 inches thick.

The O horizon has hue of 2.5YR to 7.5YR or it is neutral, value of 2, 2.5, or 3, and chroma of 1. This horizon has plant material from slightly decomposed to highly decomposed.

Figure 40.—Soil profile of the Hogback series from a hand dug pit, in the town of Lewis, in a mixed spruce, fir, and hardwood forest. In this profile, the dark reddish brown spodic subsoil, lying below a thin gray albic horizon, continues to the bedrock contact at the knife point.

The A horizon, where present, has hue of 5YR to 10YR, value of 2, 2.5, or 3, and chroma of 1 or 2. Texture is fine sandy loam, very fine sandy loam or loam in the fine-earth fraction. The horizon is 0 to 7 inches thick.

The E horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 1 or 2. Texture is loamy coarse sand, loamy sand, loamy fine sand, sandy loam, fine sandy loam, very fine sandy loam or loam in the fine-earth fraction.

The Bhs horizon has hue of 2.5YR to 7.5YR, with value and chroma of 3 or less. Some pedons have Bh horizons that have hue of 2.5YR to 10YR or are neutral and have value and chroma of 2.5 or less. Some pedons have a Bs horizon with hue of 5YR to 10YR, with value of 3 to 5 and chroma of 4 to 6. The B horizon is coarse sandy loam, sandy loam, fine sandy loam, very fine sandy loam or loam in the fine-earth fraction. B horizons range from non-smeary to moderately smeary.

Some pedons have a BC horizon that has hue of 2.5Y, value of 4 or 5 and chroma of 4.

Bedrock is slightly weathered schist, gneiss, phyllite, granite, or anorthosite.

Hollis Series

The Hollis series consists of shallow, well drained soils on summits, shoulders, and backslopes of hills and ridges in the Champlain Valley. Hollis soils formed in loamy sediments deposited by glacial ice, and are underlain by massive meta-igneous bedrock. Slopes range from 3 to 60 percent.

Hollis soils are associated on the landscape with Chatfield, Charlton, Pittsfield, Vergennes, Kingsbury, Windsor, and Collamer soils. Chatfield soils are 20 to 40 inches deep to meta-igneous bedrock. Charlton and Pittsfield soils are very deep.

Vergennes and Kingsbury soils are very deep, clayey, and are moderately well drained and somewhat poorly drained respectively. Windsor soils are very deep, sandy, and excessively drained. Collamer soils are very deep, silty clay, and moderately well drained.

Typical pedon of Hollis loam, in a map unit of Chatfield-Hollis complex, 8 to 15 percent slopes, very rocky, very stony, in the Town of Westport, 30 feet east of a point on Geismer Road that is 1,000 feet north of the junction of the Geismer Road and the Elizabethtown-Wadhams Road, in a forested area; USGS Port Henry, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 13 minutes 58 seconds N. and long. 73 degrees 29 minutes 37 seconds W.

Oi—0 to 2 inches, dark brown (10YR 3/3) slightly decomposed (fibric) plant material; weak medium granular structure; very friable; many fine and medium roots; very strongly acid; abrupt smooth boundary.

A—2 to 6 inches, dark brown (10YR 3/3) loam; weak fine and medium granular structure; very friable; many fine and medium roots; 5 percent rock fragments; strongly acid; abrupt smooth boundary.

Bw—6 to 13 inches, yellowish brown (10YR 5/8) gravelly fine sandy loam; weak fine and medium subangular blocky structure; very friable; many fine and medium roots; 25 percent rock fragments; strongly acid; abrupt smooth boundary.

R—13 inches, meta-igneous bedrock.

The thickness of the solum and depth to bedrock range from 10 to 20 inches. Rock fragments commonly range from 5 to 35 percent by volume but some pedons have less than 5 percent rock fragments. The fragments are mostly subrounded gravel except where the surface is stony. The soil has 20 percent or more silt in the particle-size control section. Unless limed, reaction ranges from extremely acid to moderately acid in the organic horizons and very strongly acid to moderately acid in the mineral horizons.

The O horizon ranges from slightly decomposed plant material to highly decomposed plant material.

The A horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is sandy loam, fine sandy loam, or loam in the fine-earth fraction. Consistence is friable or very friable.

Some pedons have a BA horizon.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 4 or 5, and chroma of 4 to 8. Texture is sandy loam, fine sandy loam, or loam in the fine-earth fraction. The Bw horizon has weak granular or weak to moderate subangular blocky structure. Consistence is friable or very friable.

Some pedons have a thin BC or C horizon with color like the Bw horizon, except it includes hue of 5Y. Texture, structure, and consistence are similar to the Bw horizon.

The R horizon is dominantly schist, granite, or gneiss bedrock. In places, this horizon is massive, but it dominantly has vertical and horizontal fractures in the upper 12 to 30 inches, but lacks significant displacement below the upper few inches.

Howard Series

The Howard series consists of very deep, well drained soils on kame terraces, beach ridges, and outwash fans in the Champlain Valley. Howard soils formed in stratified, water deposited, gravelly sediments, and are sometimes underlain by firm, loamy, calcareous basal till especially on beach ridge positions. Slopes range from 2 to 25 percent.

Howard soils are associated on the landscape with Nellis, Amenia, Bombay, Claverack, Kingsbury, Dunkirk, and Farmington soils. Nellis soils are loamy and are well drained. Amenia and Bombay soils are loamy and moderately well drained.

Claverack soils are sandy over clayey and are moderately well drained. Kingsbury soils are clayey and somewhat poorly drained. Dunkirk soils are silty clay and well drained. Farmington soils are loamy, 10 to 20 inches deep to limestone bedrock, and are well drained.

Typical pedon of Howard very cobbly loam, 15 to 25 percent slopes, in the town of Ticonderoga, 850 feet southeast of the junction of Vineyard Road and Burm Baughn Road, on the edge of a gravel pit; USGS Crown Point, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 54 minutes 22 seconds N. and long. 73 degrees 26 minutes 40 seconds W.

Oe—0 to 1 inch, very dark gray (10YR 3/1) moderately decomposed (hemic) plant material; weak fine granular structure; very friable; many fine roots; moderately acid; clear smooth boundary.

A—1 to 4 inches, very dark grayish brown (10YR 3/2) very cobbly loam; light brownish gray (10YR 6/2 dry); moderate fine and medium granular structure; very friable; many fine, and few medium and coarse roots; 35 percent rock fragments; slightly acid; clear wavy smooth boundary.

E—4 to 11 inches, yellowish brown (10YR 5/4) cobbly loam; very pale brown (10YR 7/3) dry; weak thin and medium platy parting to weak fine granular structure; very friable; common fine, and few medium and coarse roots; few medium and many fine pores; 30 percent rock fragments; neutral; gradual wavy boundary.

B/E-—11 to 15 inches, 90 percent dark brown (10YR 3/3) (B part) and 10 percent brown (10YR 5/3) (E part) very cobbly loam; E part is very pale brown (10YR 7/3) dry; weak fine and medium subangular blocky structure; very friable; common fine, and few medium and coarse roots; common fine pores; common faint clay linings in pores, and few faint clay bridges of pebbles and sand grains; 40 percent rock fragments; neutral; gradual irregular boundary.

Bt—15 to 22 inches, dark brown (10YR 3/3) very cobbly loam; weak medium and fine subangular blocky structure; very friable, slightly sticky and slightly plastic; common fine and few medium roots; common fine pores; thin discontinuous clay films on ped surfaces, distinct continuous clay linings in pores, many clay bridges of small pebbles and sand grains, and patchy clay films on underside of some rock fragments; 45 percent rock fragments; neutral; clear irregular boundary.

2C1—22 to 35 inches, brown (10YR 4/3) extremely cobbly loamy sand; single grain; loose; few fine roots; 60 percent rock fragments; moderately alkaline, strongly effervescent; gradual wavy boundary.

2C2—35 to 72 inches, dark grayish brown (10YR 4/2) extremely cobbly loamy sand; single grain; loose; 70 percent rock fragments; moderately alkaline, strongly effervescent.

The thickness of the solum and depth to carbonates range from 22 to 60 inches. Bedrock is at depths greater than 60 inches. Rock fragments, mainly gravel and cobbles, range from 5 to 35 percent by volume in the surface layer, from 15 to 55 percent in the upper part of the subsoil, from 35 to 60 percent in the lower part of the subsoil, and from 45 to 70 percent in the substratum. The soil ranges from strongly acid to neutral in the solum and neutral to moderately alkaline in the substratum.

The Ap horizons have hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 2 or 3. Texture ranges from sandy loam to silt loam in the fine-earth fraction. They have weak or moderate, fine or medium granular structure and very friable or friable consistence. Some pedons have an A horizon up to 6 inches thick.

The E horizons have hue of 5YR to 10YR, value of 4 to 6, and chroma of 2 to 4. Texture ranges from sandy loam to silt loam in the fine-earth fraction. They have weak, fine or medium granular, blocky, or platy structure, or the material is massive. Consistence is very friable, friable or firm. In some pedons, the E horizon is replaced by a BE horizon with chroma of 4 or 6. Some pedons have an EB horizon.

The E/B and B/E horizons are transitional from the E to Bt horizons in color and texture. Structure is weak to moderate, fine or medium granular, subangular blocky or platy, and consistence is very friable or friable.

The Bt horizons have hue of 5YR to 10YR, value of 2 to 5, and chroma of 3 or 4. Texture is sandy loam, fine sandy loam, loam, silt loam, clay loam, or sandy clay loam in the fine earth fraction. They have weak or moderate, fine to coarse, angular or subangular blocky structure, and have very friable to firm consistence.

The 2C horizon has hue of 2.5YR to 5Y, value of 3 to 6, and chroma of 2 to 4. Texture is coarse sand, sand, loamy sand or loamy fine sand in the fine-earth fraction and is most commonly stratified. In some pedons a C1 or BC horizon up to 12 inches thick may lack free carbonates. The C horizon has textures of sandy loam or fine sandy loam in the fine-earth fraction.

Some pedons have a loamy 3C horizon that has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 1 to 4. Texture is silt loam, loam, very fine sandy loam or fine sandy loam in the fine earth fraction. Structure is massive with or without plate-like divisions. Consistence is firm or very firm. Reaction is slightly alkaline through strongly alkaline.

Correlation Note: The HlB, HlC, and HmB map units have textures below 40 inches that are finer than typical for the range of the Howard series. This should not significantly affect use and management on a local basis for most purposes.

Kalurah Series

The Kalurah Series consists of very deep, moderately well drained soils on side slopes and footslopes of glaciated hills and ridges, and on till plains in the eastern foothills of the Adirondack High Peaks Region. Kalurah soils formed in loamy sediments underlain by firm, loamy, calcareous lodgment till. Slopes range from 3 to 15 percent.

Kalurah soils are associated on the landscape with Pyrites, Nehasne, Malone, Typic Endoaquolls, Wonsqueak, Tunbridge, and Lyman soils. Pyrites soils are well drained. Nehasne soils are 20 to 40 inches deep over marble bedrock. Malone soils are somewhat poorly drained. Typic Endoaquolls soils are poorly drained. Wonsqueak soils are mucky and are very poorly drained. Tunbridge soils are well drained, more acid and are 20 to 40 inches deep to meta-igneous bedrock. Lyman soils are well drained, more acid and are 10 to 20 inches deep to meta-igneous bedrock.

Typical pedon of Kalurah silt loam, 3 to 8 percent slopes, in an idle area near a sawmill, town of Moriah, about 1,300 feet south of the West Moriah Road-South Moriah Road intersection and about 200 feet west of South Moriah Rd; USGS Elizabethtown 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 02 minutes 33 seconds N. and long. 73 degrees 30 minutes 21 seconds W.

Ap—0 to 9 inches, very dark grayish brown (10YR 3/2) silt loam; pale brown (10YR 6/3) dry; moderate fine granular structure; very friable; common medium and coarse roots; many fine roots; 10 percent rock fragments; moderately acid; clear wavy boundary.

Bw1—9 to 13 inches, dark yellowish brown (10YR 4/4) gravelly loam; weak medium subangular blocky structure; very friable; common fine roots and few medium roots; 15 percent rock fragments; slightly acid; gradual irregular boundary.

Bw2—13 to 22 inches, brown (10YR 4/3) gravelly loam; weak medium and fine subangular blocky structure; very friable; common fine roots and few medium roots; 15 percent rock fragments; slightly acid; clear wavy boundary.

BC—22 to 32 inches, brown (10YR 5/3) gravelly fine sandy loam; weak medium subangular blocky parting to weak thin platy structure; some stripped sand grains evident; friable; few fine, medium and coarse roots; common fine vesicular and tubular pores; 20 percent rock fragments; common medium distinct yellowish

brown (10YR 5/6) masses of iron accumulation, and few fine faint light brownish gray (10YR 6/2) and grayish brown (10YR 5/2) depletions; slightly acid; clear wavy boundary.

C1—32 to 47 inches, dark grayish brown (10YR 4/2) and brown (10YR 4/3) gravelly fine sandy loam; massive with strong thin plate like divisions; firm; few fine roots; 20 percent rock fragments; common fine and medium distinct yellowish brown (10YR 5/6) masses of iron accumulation, and common fine and medium distinct light brownish gray (2.5Y 6/2) depletions; neutral; gradual wavy boundary.

C2—47 to 72 inches, brown (10YR 5/3) gravelly sandy loam; massive with moderate thin and medium plate like divisions; friable; 25 percent rock fragments; few medium faint light brownish gray (2.5Y 6/2) iron depletions, and few medium faint dark yellowish brown (10YR 4/4) masses of iron accumulation; neutral.

The thickness of the solum ranges from 30 to 50 inches. Depth to carbonates is greater than 40 inches. Depth to bedrock is greater than 60 inches. Rock fragments, mostly gravel, range from 5 to 35 percent in the solum and from 5 to 50 percent in the C horizon.

The Ap horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 2 or 3. Texture of the fine-earth fraction is commonly fine sandy loam and less commonly loam or silt loam. Reaction ranges from moderately acid to neutral.

The Bw horizon has hue of 7.5YR or 10YR, value of 4 or 5, and chroma of 2 to 6, with chroma of 2 matrix or faces of peds restricted to depths greater than 20 inches. A portion of the Bw or BC above a depth of 24 inches has redoximorphic depletions with chroma of 2 or less. Texture of the fine-earth fraction is commonly fine sandy loam and less commonly sandy loam, loam or silt loam. Reaction is slightly acid or neutral. Some pedons have a BC horizon.

The C horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 2 to 6. Texture of the fine-earth fraction is fine sandy loam, sandy loam, or loam. Some pedons have thin layers of loamy sand. Below 60 inches, some pedons have a silt loam texture. Consistence is friable or firm. Reaction ranges from neutral to moderately alkaline.

Kingsbury Series

The Kingsbury series consists of very deep, somewhat poorly drained soils on lake plains in the Champlain Valley. Kingsbury soils formed in clayey sediments deposited in still water that was fresh or brackish. Slopes range from 0 to 8 percent.

Kingsbury soils are associated on the landscape with Vergennes, Covington, Livingston, Cayuga, Amenia, Windsor, and Farmington soils. Vergennes soils are moderately well drained. Covington soils are poorly drained. Livingston soils are very poorly drained. Cayuga soils are clayey over loamy and are moderately well drained. Amenia soils are loamy and moderately well drained. Windsor soils are sandy and excessively drained. Farmington soils are loamy, 10 to 20 inches deep to limestone bedrock, and are well drained (fig. 41).

Typical pedon of Kingsbury silty clay loam, 0 to 3 percent slopes, in a hay field, in the town of Crown Point, .3 miles east of junction of Burdick Road and Route 9N, and .2 miles north of Burdick Road; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 59 minutes 00 seconds N. and long. 73 degrees 26 minutes 32 seconds W.

Ap—0 to 9 inches, dark grayish brown (10YR 4/2) silty clay loam; light brownish gray (10YR 6/2) dry; moderate fine and medium granular structure; friable; slightly sticky and plastic; many fine and few medium roots; neutral; abrupt smooth boundary.

Bt1—9 to 14 inches, brown (10YR 4/3) clay; dark grayish brown (2.5Y 4/2) ped faces; moderate medium subangular blocky structure; firm; sticky and plastic; common

Figure 41.—Soil profile of the Kingsbury series from a backhoe test pit, in the town of Crown Point, in a hay field. Note the mottled appearance of this very clayey soil. The blue-gray colors, or "redoximorphic depletions" are formed from seasonal saturation, and reduction and translocation of iron.

fine and very fine roots; many fine vesicular and common fine tubular pores; thin discontinuous clay films on ped surfaces and pore linings; few fine faint dark yellowish brown (10YR 4/4) soft masses of iron accumulation; neutral; clear wavy boundary.

Bt2—14 to 21 inches, grayish brown (10YR 5/2) clay; moderate fine and very fine angular blocky structure; firm; sticky and plastic; few very fine roots; many fine vesicular and common fine tubular pores; moderately thick continuous clay films on ped surfaces; many fine and medium distinct dark yellowish brown (10YR 4/4 and 4/6) and few fine prominent strong brown (7.5YR 4/6) soft masses of iron accumulation; neutral; clear wavy boundary.

CB—21 to 34 inches, grayish brown (10YR 5/2) silty clay; weak coarse prismatic parting to weak fine and medium subangular blocky structure; firm; sticky and plastic; few fine roots along prism faces; 1 percent pebbles; common faint light gray (10YR 7/2) carbonate coats on prism faces and few firm carbonate nodules; many fine and medium faint dark yellowish brown (10YR 4/4) and common fine distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; moderately alkaline, strongly effervescent; clear wavy boundary.

C1-—34 to 65 inches, brown (10YR 4/3) clay; gray (10YR 5/1) desiccation crack surfaces; massive with desiccation cracks; firm; sticky and plastic; few fine roots along desiccation crack surfaces; 1 percent pebbles; few fine vesicular and tubular pores; common distinct light gray (10YR 7/2) carbonate coats on prism faces and

few firm carbonate nodules; common medium faint yellowish brown (10YR 5/4) soft masses of iron accumulation; moderately alkaline, strongly effervescent; clear irregular boundary.

C2—65 to 93 inches, brown (10YR 4/3) silty clay; gray (N5/) desiccation crack surfaces; massive with some desiccation cracks; firm; sticky and plastic; 1 percent pebbles; moderately alkaline, violently effervescent.

The thickness of the solum ranges from 20 to 36 inches. Depth to carbonates ranges from 20 to 60 inches. Depth to bedrock is more than 60 inches. Rock fragments range from 0 to 3 percent. Reaction ranges from strongly acid to slightly alkaline in the solum.

The A or Ap horizons have hue of 10YR to 5Y, value of 2 to 5, and chroma of 1 to 3. Texture is silt loam, but range from very fine sandy loam to clay. These horizons have granular or subangular blocky or angular blocky structure and very friable to firm consistence.

Some pedons have an E horizon that has hue of 10YR to 5Y, value of 3 to 6, and chroma of 2 to 4, and have redoximorphic features. Texture ranges from silt loam or very fine sandy loam to silty clay. It has angular or subangular blocky to platy structure and friable or firm consistence.

The Bt horizon has hue of 10YR to 5Y, value of 3 to 5, and chroma of 2 to 4. The horizon typically has greater than 50 percent redoximorphic depletions on ped faces with redoximorphic concentrations in ped interiors. Texture ranges from silty clay loam to clay in individual subhorizons but averages clay. It has angular or subangular blocky structure, within coarse or very coarse prisms in some pedons. The Bt horizon is firm or very firm. Some pedons have a BC or CB horizon.

The C horizon has colors similar to Bt horizons, except redoximorphic features are commonly of lower contrast. Texture ranges from silty clay loam to clay. The C horizons are massive, with varves in many pedons. Some pedons have coarse prismatic structure that is massive within prisms. When disturbed, the material in many pedons parts into aggregates resembling angular blocky structure, but lack the coatings of oriented clay found in the Bt horizons.

Knob Lock Series

The Knob Lock series consists of very shallow and shallow, well drained to excessively drained soils on summits, shoulders, and backslopes of glaciated mountains, hills, and ridges in the Adirondack Upland. Knob Lock soils formed in decomposing plant material, sometimes underlain by a thin (up to 4 inches) mineral soil layer, directly over meta-igneous bedrock. Slopes range from 15 to 60 percent.

Knob Lock soils are associated on the landscape with Tunbridge, Rawsonville, Lyman, and Hogback soils. Tunbridge and Rawsonville soils are loamy and are moderately deep to bedrock. Lyman and Hogback soils are loamy and are shallow to bedrock.

Typical pedon of Knob Lock peat, in a map unit of Hogback-Knob Lock complex, 35 to 60 percent slopes, in a forested area, in the town of Keene, summit of Blueberry Mountain, about 2.5 miles northwest of the hamlet of Keene Valley; USGS Mt. Marcy 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees, 13 minutes, 03 seconds N. and long. 73 degrees, 48 minutes, 56.6 seconds W.

Oe—0 to 3 inches; dark reddish brown (5YR 2.5/2) broken, crushed and rubbed moderately decomposed plant (hemic) material; about 45 percent fiber, 27 percent rubbed; weak fine granular structure; friable; many fine, very fine and medium roots; extremely acid; clear smooth boundary.

Oa—3 to 7 inches; black (5YR 2.5/1) broken, crushed and rubbed highly decomposed plant (sapric) material; about 27 percent fiber, 15 percent rubbed; weak fine and

medium granular structure; friable; many fine and very fine, and common medium roots; extremely acid; clear smooth boundary.

Bs—7 to 9 inches; dark reddish gray (5YR 4/2) very fine sandy loam; weak medium and fine subangular blocky structure; friable; common very fine and fine, and few medium roots; very strongly acid; abrupt smooth boundary.

R—9 inches; Marcy Anorthosite.

The depth to bedrock ranges from 1 to 20 inches. Very thin mineral layers are at the bedrock interface in most pedons. Rock fragments range from 0 to 50 percent in the mineral layers. The organic and mineral layers are extremely acid or very strongly acid.

The Oi horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 4, and chroma of 0 to 4. The horizon is slightly decomposed plant (fibric) material.

The Oe horizon is neutral or has hue of 2.5YR to 10YR, value of 2 or 3, and chroma of 0 to 6. It is moderately decomposed plant (hemic) material.

The Oa horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 5, and chroma of 0 to 2. It is highly decomposed plant (sapric) material.

The mineral horizons have hue of 5YR to 5B, value of 2 to 7, and chroma of 1 to 3. They are A, E, Bh, Bhs, or C horizons. Texture is coarse sand, sand, loamy sand, loamy fine sand, sandy loam, fine sandy loam, very fine sandy loam, or loam in the fine-earth.

Livingston Series

The Livingston series consists of very deep, very poorly drained soils in depressions on lake plains in the Champlain Valley. Livingston soils formed in clayey sediments deposited in still water that was fresh or brackish. Slopes range from 0 to 3 percent.

Livingston soils are associated on the landscape with Vergennes, Kingsbury, Covington, Cayuga, Churchville, Amenia, and Whallonsburg soils. Vergennes soils are moderately well drained. Kingsbury soils are somewhat poorly drained. Covington soils are poorly drained. Cayuga soils are clayey over loamy and are moderately well drained. Churchville soils are clayey over loamy and are somewhat poorly drained. Whallonsburg soils are mucky.

Typical pedon of Livingston mucky silty clay loam, 0 to 3 percent slopes, in the town of Essex, 250 feet south of the intersection of Middle Road and School Road, then 756 feet west of Middle Road (10 feet north of fence line), in a pasture; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 17 minutes 50 seconds N. and long. 73 degrees 22 minutes 48 seconds W.

Ap—0 to 9 inches, very dark gray (N 3/0) mucky silty clay loam; gray (N 5/0) dry; strong fine granular structure; friable, slightly sticky, slightly plastic; common fine and medium roots, few coarse roots; neutral; clear smooth boundary.

Bg1—9 to 21 inches, gray (N 5/0) clay; weak very coarse prismatic structure parting to moderate fine and medium angular blocky structure; firm, very sticky, very plastic; few fine roots; few fine pores; common medium prominent brown (7.5YR 4/4) soft masses of iron accumulation; neutral; gradual wavy boundary.

Bg2—21 to 35 inches, gray (5Y 5/1) clay; weak very coarse prismatic structure parting to moderate fine and medium angular blocky structure; firm, very sticky, very plastic; few fine roots; few fine pores; many medium and fine prominent strong brown (7.5YR 4/6) and dark yellowish brown (10YR 4/4) soft masses of iron accumulation; neutral; gradual smooth boundary.

BCg—35 to 46 inches, gray (N 5/0 and 5Y 5/1) clay; weak thick platy structure; firm, sticky, plastic; few fine pores; many medium and coarse distinct olive (5Y 5/4) soft masses of iron accumulation; neutral; gradual wavy boundary.

Cg1—46 to 56 inches, grayish brown (2.5Y 5/2) clay; massive with varves; sticky, plastic; few fine pores; some gray (N 5/0) plate faces; common medium and coarse

distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation; slightly alkaline, slightly effervescent; gradual smooth boundary.

Cg2—56 to 72 inches, dark gray (10YR 4/1) and dark grayish brown (10YR 4/2) clay; massive with varves; sticky, plastic; few fine pores; some gray (10YR 6/1) ped surfaces; common medium and coarse prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; moderately alkaline, strongly effervescent.

The thickness of solum ranges from 30 to 48 inches. Depth to bedrock is greater than 60 inches. Reaction ranges from strongly acid to slightly alkaline in the A and Bg horizons, is neutral or slightly alkaline in the BCg horizon, and ranges from slightly alkaline to moderately alkaline in the Cg horizon. Flooded and depressional phases of the Livingston series are recognized.

The A horizon is neutral or has hue of 5YR to 5Y, value of 2 to 3, and chroma of 0 or 1. Texture is clay, silty clay, silty clay loam, or their mucky analogs. Structure is moderate or strong, very fine to coarse granular or very fine subangular blocky. Consistence is very friable or friable. It is sticky and plastic.

The Bg and BCg horizon are neutral or have hue of 10YR to 5Y, value of 4 or 5, and chroma of 0 to 2. Texture is clay. Structure is weak to strong, medium to very coarse prismatic or weak to strong, very fine to medium subangular or angular blocky, or weak or moderate, medium or thick platy. Consistence is firm or very firm. It is sticky or very sticky, plastic or very plastic.

The Cg horizon is neutral or has hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 or 2. Some strata may range to chroma of 4 in the BCg and Cg horizons. Texture is clay. Structure is moderate or strong, fine or medium, angular or subangular blocky, or is massive with varves. Consistence is firm or very firm It is sticky or very sticky, plastic or very plastic.

Lovewell Series

The Lovewell series consists of very deep, moderately well drained soils on flood plains. Lovewell soils formed in alluvial sediments dominated by very fine sand and silt. Slopes range from 0 to 3 percent.

Lovewell soils are in a drainage sequence with the somewhat poorly drained Cornish soils and the very poorly drained Medomak soils. Lovewell soils are also associated on the landscape with Monadnock, Kalurah, Adams, Colton, and Wonsqueak soils. Lovewell soils have fewer rock fragments than Monadnock and Kalurah soils. Lovewell soils have an irregular decrease in organic carbon content relative to depth whereas Adams and Colton soils decrease in organic carbon with depth. Lovewell soils do not have a thick organic accumulation as is characteristic of Wonsqueak soils.

Typical pedon of Lovewell very fine sandy loam, 0 to 3 percent slopes, in the town of Champlain, Clinton County NY, about 250 feet north of intersection of Simmons Road with St. John’s Road, and 2,600 feet east of St. Johns’s Road in a cornfield; USGS Mooers, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 44 degrees 57 minutes 14 seconds N. and long. 73 degrees 30 minutes 31 seconds W.

Ap—0 to 11 inches; dark brown (10YR 3/3) very fine sandy loam, pale brown (10YR 6/3) dry; weak coarse subangular blocky parting to weak medium granular structure; friable; common very fine roots; moderately acid; abrupt smooth boundary.

Bw1—11 to 20 inches; yellowish brown (10YR 5/4) very fine sandy loam; weak coarse and medium subangular blocky structure; friable; few very fine roots; moderately acid; clear wavy boundary.

Bw2—20 to 30 inches; yellowish brown (10YR 5/4) very fine sandy loam, grayish brown (10YR 5/2) face of prisms; weak very coarse prismatic parting to weak

coarse subangular blocky structure; friable; few very fine roots; common medium distinct grayish brown (10YR 5/2) areas of iron depletion, and common medium faint dark yellowish brown (10YR 4/4) masses of iron oxides; strongly acid; clear smooth boundary.

Cg1—30 to 50 inches; light brownish gray (10YR 6/2) very fine sandy loam; massive; friable; many medium distinct dark yellowish brown (10YR 4/4) and many medium prominent dark yellowish brown (10YR 4/6), and common fine prominent yellowish brown (10YR 5/6) masses of iron oxides; very strongly acid; abrupt smooth boundary.

Cg2—50 to 56 inches; grayish brown (10YR 5/2) fine sand; weak thick platy structure; very friable; many medium and coarse distinct yellowish brown (10YR 5/4) and medium and coarse prominent yellowish brown (10YR 5/6) masses of iron oxides; strongly acid; clear smooth boundary.

Cg3—56 to 75 inches; gray (10YR 5/1) fine sand; massive; very friable; many coarse distinct dark yellowish brown (10YR 3/4) masses of iron oxides; strongly acid.

The thickness of the solum ranges from 20 to 30 inches. Gravel content ranges from 0 to 5 percent by volume to a depth of 40 inches and from 0 to 20 percent below 40 inches. Redox depletions are between depths of 16 to 24 inches. The soil ranges from very strongly acid to slightly acid, unless limed. Some pedons have buried horizons.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 to 4. Dry value is 6 or 7.Texture is silt loam or very fine sandy loam. Structure is weak to strong, very fine to coarse, granular or subangular blocky. Consistence is very friable or friable.

The B horizon has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 2 to 6. Texture is silt loam or very fine sandy loam. Structure is weak or moderate, fine to coarse, granular or subangular blocky. Some pedons have platy or prismatic structure. Consistence is very friable or friable. A CB horizon is present in some pedons between the B and C horizons.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 4. Texture is silt loam, very fine sandy loam, or loamy very fine sand. Some pedons have strata below 40 inches that range from silt loam to fine gravel. The C horizon is massive or single grain, depending upon texture, or has platy structure. Consistence ranges from loose to friable.

Lyman Series

The Lyman series consists of shallow, somewhat excessively drained soils on summits, shoulders, and backslopes of glaciated mountains, hills, and ridges in the Adirondack Upland. Lyman soils formed in loamy sediments deposited by glacial ice, and are underlain by meta-igneous bedrock. Slopes range from 3 to 60 percent.

Lyman soils are associated on the landscape with Tunbridge, Knob Lock, Becket, Monadnock, Skerry, Adirondack, and Tahawus soils. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock and are well drained. Knob Lock soils are mucky, 2 to 20 inches deep to meta-igneous bedrock, and are well to excessively drained. Becket soils are very deep and well drained. Monadnock soils are loamy over sandy or gravelly, very deep, and well drained. Skerry soils are very deep and moderately well drained. Adirondack soils are very deep and somewhat poorly drained. Tahawus soils are sandy, very deep, and very poorly drained (fig. 42).

Typical pedon of Lyman gravelly sandy loam, in a map unit of Tunbridge-Lyman complex, 15 to 35 percent slopes, very rocky, very bouldery, in the town of Wilmington, 2.1 miles South on Bartlett Road from intersection with County Route 12, then .45 mile West on Bartlett Road (before crossing Liscomb Brook), 1,500 feet due north through woods onto bedrock ridge, in a stand of northern red oak and red pine; USGS Lake Placid, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 18 minutes, 34 seconds N. and long. 73 degrees, 48 minutes, 54 seconds W.

Figure 42.—Soil profile of the Lyman series from a hand dug pit, in the town of Jay, in a mixed pine and hardwood forest. This profile, which is about 14 inches deep, has a very thin gray albic horizon, and a more weakly developed reddish brown spodic horizon than the higher elevation Hogback soils.

Oi—0 to 1/2 inch, slightly decomposed needles, leaves, and twigs.

Oe—1/2 to 1 inch, very dark brown (10YR 2/2) moderately decomposed (hemic) plant material; structureless; very friable; many fine and very fine roots, common medium roots; 5 percent rock fragments (gravel and cobbles); very strongly acid; abrupt smooth boundary.

Oa—1 to 2 inches, black (10YR 2/1) highly decomposed (sapric) plant material; massive or weak fine granular structure; very friable; many fine and very fine roots, common medium roots, few coarse roots; 10 percent rock fragments (gravel and cobbles); very strongly acid; abrupt smooth boundary.

E—2 to 3 inches, gray (5YR 6/1) gravelly sandy loam; massive; very friable; many fine and very fine roots, few medium and coarse roots; 10 percent gravel, 5 percent cobbles, 1 percent stones; very strongly acid; abrupt wavy boundary.

Bs—3 to 9 inches, brown (7.5YR 4/4 and 5/4) gravelly sandy loam, weak fine granular structure; friable; many fine and very fine roots, few medium and coarse roots; 10 percent gravel, 5 percent cobbles, 1 percent stones; very strongly acid; clear wavy boundary.

BC1—9 to 13 inches, yellowish brown (10YR 5/4) gravelly sandy loam; weak fine subangular blocky structure; friable; common fine and very fine roots, few medium and coarse roots; 15 percent gravel, 5 percent cobbles, 1 percent stones; strongly acid; gradual wavy boundary.

BC2—13 to 18 inches, brown (10YR 5/3) gravelly sandy loam; massive; friable; common fine and very fine roots, few medium and coarse roots; 20 percent gravel, 5 percent cobbles, 1 percent stones; strongly acid.

R—18 inches, Marcy Anorthosite.

Mineral solum thickness ranges from 10 to 20 inches and corresponds to the depth to bedrock. Rock fragments consist of 5 to 25 percent gravel and 0 to 10 percent cobbles throughout, and 0 to 15 percent stones in the A horizon and 0 to 3 percent

stones in the B horizon. Rock fragments are schist with lesser amounts of phyllite, granite, and gneiss. The soil ranges from extremely acid to moderately acid throughout, unless limed.

The O horizon consists of fibric, hemic and/or sapric material.

The A horizon is neutral or has hue of 5YR to 10YR, value of 2, 2.5 or 3, and chroma of 0 to 2. Some pedons have Ap horizons with value and chroma of 2 to 4. Ap horizons are typically 6 inches or more thick. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam or silt loam in the fine-earth fraction.

The E horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 1 or 2. Texture is loamy sand, loamy fine sand, sandy loam, fine sandy loam, very fine sandy loam, loam or silt loam in the fine-earth fraction.

The Bhs horizon has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 1 to 3.

The Bs horizon has hue of 5YR to 10YR, value of 3 to 5, and chroma of 3 to 8. Some pedons have a Bh horizon with chroma of 5YR to 10YR, value of 2 to 3 and chroma of 1 to 4. Texture of the Bhs, Bs, and Bh is sandy loam, fine sandy loam, very fine sandy loam, loam or silt loam in the fine-earth fraction.

Some pedons have a BC horizon with hue of 10YR to 5Y, value of 3 to 5, and chroma of 3 or 4. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam in the fine-earth fraction.

The R or 2R layer is generally dark gray, greenish gray or nearly black mica schist bedrock but in places the underlying bedrock is phyllite, granite or gneiss.

Malone Series

The Malone series consists of very deep, somewhat poorly drained soils on footslopes and saddles of glaciated hills and ridges and on till plains in the eastern foothills of the Adirondack High Peaks Region. Malone soils formed in loamy sediments underlain by firm, loamy, calcareous lodgment till. Slopes range from 3 to 8 percent.

Malone soils are associated on the landscape with Kalurah, Typic Endoaquolls, Wonsqueak, Pyrities, Nehasne, and Tunbridge soils. Kalurah soils are moderately drained. Typic Endoaquolls soils are poorly drained. Wonsqueak soils are very poorly drained, and have a thick mucky surface. Pyrities soils are well drained. Nehasne soils are well drained, and are 20 to 40 inches deep to marble bedrock. Tunbridge soils are acid, well drained, and are 20 to 40 inches deep to meta-igneous bedrock.

Typical pedon of Malone silt loam, 3 to 8 percent slopes, in an idle hay field, town of Crown Point, 700 feet west of a point on Whitehead Road, that is 2,300 feet south of the junction of Whitehead Road and North Road; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 55 minutes 47 seconds N. and long. 73 degrees 32 minutes 35 seconds W.

Ap—0 to 7 inches; very dark grayish brown (10YR 3/2) silt loam, light brownish gray (10YR 6/2) dry; strong fine and medium granular structure; friable; many fine and very fine roots; 5 percent rock fragments; slightly acid; clear smooth boundary.

E—7 to 12 inches; dark grayish brown (10YR 4/2) silt loam; moderate fine and medium subangular blocky structure; friable; many fine and very fine roots; 5 percent rock fragments; many fine prominent yellowish red (5YR 4/6) masses of iron accumulation; neutral; clear smooth boundary.

Bw1—12 to 17 inches; dark yellowish brown (10YR 4/4 and 4/6) loam; moderate fine and medium subangular blocky structure; friable; common fine and very fine roots; common fine tubular pores; 7 percent rock fragments; few fine distinct strong brown (7.5YR 5/8) masses of iron accumulation, and few fine distinct light brownish gray (10YR 6/2) iron depletions; neutral; clear smooth boundary.

Bw2—17 to 25 inches; brown (10YR 4/3) loam; moderate medium and coarse subangular blocky structure; friable; few fine roots; common fine and medium tubular and few fine vesicular pores; 7 percent rock fragments; common fine and

medium prominent yellowish brown (10YR 5/8) masses of iron accumulation and common fine and medium faint light brownish gray (10YR 6/2) iron depletions; neutral; clear smooth boundary.

Cd—25 to 72 inches; brown (10YR 5/3) loam; massive with weak thick plate-like divisions, firm; many fine tubular and common fine vesicular pores; 10 percent rock fragments; many fine and medium prominent strong brown (7.5YR 5/8) masses of iron accumulation and many fine and medium distinct gray (10YR 6/1) iron depletions; slightly effervescent, slightly alkaline.

The thickness of the solum ranges from 18 to 38 inches. Depth to carbonates range from 18 to 50 inches. Depth to bedrock is greater than 60 inches. Limestone or dolomite limestone rock fragments, gravel, cobbles, and channers range from 5 to 35 percent by volume in the solum and 5 to 50 percent in the substratum.

The Ap horizon has hue of 10YR, value of 2 to 5, and chroma of 1 to 3. Texture is silt loam, loam, fine sandy loam, or sandy loam in the fine-earth fraction. Reaction is moderately acid or slightly acid, unless limed. Some pedons have an E horizon with hue of 7.5YR or 10YR, value of 4 to 6, and chroma of 1 or 2. Texture is silt loam, loam, fine sandy loam, or sandy loam in the fine-earth fraction. Reaction is moderately acid to neutral.

The Bw horizon has hue of 5YR to 2.5Y, value 3 to 6, and chroma of 3 to 6. Texture is sandy loam, fine sandy loam, or loam in the fine-earth fraction. Reaction is slightly acid or neutral.

The Bg horizon has hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 1 or 2. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction, with thin subhorizons of silty clay loam or silt loam in some pedons. Reaction is slightly acid or neutral.

Some pedons have a BC horizon with hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 1 to 3. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction, with thin subhorizons of silty clay loam or silt loam in some pedons. Reaction is slightly acid to slightly alkaline.

The Cd horizon has hue of 10YR or 2.5Y, value of 5 or 6, and chroma of 2 to 4. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction. Reaction ranges from neutral to moderately alkaline.

Massena Series

The Massena series consists of very deep, somewhat poorly drained soils on footslopes of glaciated ridges and hills and on till plains in the Champlain Valley. Massena soils formed in loamy sediments underlain by loamy, calcareous basal till. Slopes range from 0 to 8 percent.

Massena soils are associated on the landscape with Nellis, Amenia, Bombay, Georgia, Sun, Kingsbury, and Stafford soils. Nellis soils are well drained. Amenia, Bombay, and Georgia soils are moderately well drained. Sun soils are poorly drained. Kingsbury soils are clayey. Stafford soils are sandy.

Typical pedon of Massena gravelly silt loam, 0 to 3 percent slope, in a corn field, in the town of Essex, approximately 175 feet north of Sanders Road at a point about 1.4 miles southwest of junction with West Road; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 18 minutes 34 seconds N. and long. 73 degrees 26 minutes 24 seconds W.

Ap—0 to 9 inches, very dark grayish brown (10YR 3/2) gravelly silt loam; light brownish gray (10YR 6/2) dry; moderate medium granular structure; friable; few fine and medium roots; 20 percent rock fragments; slightly acid; abrupt smooth boundary.

Bw1—9 to 18 inches, brown (10YR 5/3) loam; grayish brown (10YR 5/2) ped faces; moderate medium subangular blocky structure; friable; few fine and medium roots;

10 percent rock fragments; common fine distinct gray (10YR 5/1) iron depletions and many medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral; clear smooth boundary.

Bw2—18 to 24 inches, brown (10YR 5/3) loam; grayish brown (10YR 5/2) ped faces; moderate medium subangular blocky structure; friable; 10 percent rock fragments; few fine distinct gray (10YR 5/1) iron depletions; neutral; clear smooth boundary.

C—24 to 72 inches, brown (10YR 5/3) gravelly sandy loam; massive; friable; 20 percent rock fragments; many medium faint grayish brown (10YR 5/2) iron depletions and many medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; slightly alkaline, slightly effervescent.

The thickness of the solum ranges from 18 to 36 inches. Depth to carbonates mainly range from 20 to 50 inches, but in some pedons carbonates are deeper than 50 inches. Depth to bedrock is more than 60 inches. Rock fragments range from 5 percent to 35 percent by volume in the mineral solum and from 5 percent to 50 percent in the C horizon. Reaction ranges from moderately acid through neutral in the mineral solum, and from neutral through moderately alkaline in the C horizon.

The A or Ap horizon has hue of 7.5YR to 2.5Y, value of 3 or 4, and chroma of 1 or 2. Texture of the fine-earth fraction ranges from fine sandy loam to silt loam. Structure is weak to moderate, very fine to medium granular. Consistence is friable or very friable.

The Bw horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 3 or 4 and has redoximorphic features. Texture of the fine-earth fraction is sandy loam, fine sandy loam, or loam. Structure is medium or fine subangular blocky, or it is massive. Consistence is friable or very friable.

The Bg horizon has hue of 5YR to 2.5Y, value of 4 to 6, and chroma of 1 or 2 and has redoximorphic features. Texture of the fine-earth fraction is sandy loam, fine sandy loam, or loam. Structure is medium or fine subangular blocky, or it is massive. Consistence is friable or very friable.

Some pedons have a BC horizon with color and texture similar to that of the B horizon. Structure is medium or fine subangular blocky, or moderate, thin to medium platy.

The C or Cg horizon has hue of 5YR to 5Y, value of 4 to 6, and chroma of 1 to 4. Texture of the fine-earth fraction is sandy loam, fine sandy loam, or loam. Structure is platy or it is massive. Consistence in the upper part of the horizon is friable, but is firm in the lower part of some pedons.

Some pedons have 2C, 2Cg, or 3Cg horizons.

Medomak Series

The Medomak series consists of very deep, very poorly drained soils on flood plains in intermontane valleys of the Adirondack Upland. Medomak soils formed in silty sediments deposited by flood waters. Slopes range from 0 to 3 percent.

Medomak soils are associated on the landscape with Lovewell, Cornish, Charles, Adams, Depeyster, and Becket soils. Lovewell soils are moderately well drained. Cornish soils are somewhat poorly drained. Charles soils are poorly drained. Adams soils are sandy and somewhat excessively drained. Depeyster soils are silty clay and moderately well drained. Becket soils are loamy and well drained.

Typical pedon of Medomak mucky silt loam, 0 to 3 percent slopes, in a wooded area, in the town of Chesterfield, 0.7 miles south on Trout Pond Road (from Green Street) to intermittent stream, then 300 feet northeast along stream, then 150 feet north from stream, in woods at edge of meadow; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1927; and lat. 44 degrees 26 minutes 55 seconds N. and long. 73 degrees 34 minutes 42 seconds W.

Oi—0 to 1 inch; slightly decomposed leaves, roots, and twigs; few coarse roots.

Oa—1 to 5 inches; very dark brown (10YR 2/2) muck; massive; very friable, slightly sticky, non-plastic; many very fine and common fine roots; slightly acid; abrupt wavy boundary.

A—5 to 11 inches; very dark grayish brown (10YR 3/2) mucky silt loam, grayish brown (10YR 5/2) dry; weak fine granular structure; very friable, slightly sticky, non-plastic; common very fine and few fine roots; neutral; clear irregular boundary.

Cg1—11 to 20 inches; dark gray (2.5Y 4/1) silt loam; massive; friable, slightly sticky and slightly plastic; common medium faint grayish brown (2.5Y 5/2) iron depletions; neutral; clear wavy boundary.

Cg2—20 to 29 inches; gray (2.5Y 5/1) very fine sandy loam; massive; very friable, slightly sticky, non-plastic; neutral; abrupt wavy boundary.

A'—29 to 31 inches; very dark brown (7.5YR 2.5/2) mucky very fine sandy loam; massive; very friable, slightly sticky, non-plastic; neutral; abrupt wavy boundary.

Cg1'—31 to 41 inches; gray (2.5Y 6/1) very fine sandy loam; massive; very friable, slightly sticky, non-plastic; common medium prominent yellowish brown (10YR 5/6) masses of iron accumulation; neutral; clear wavy boundary.

Cg2'—41 to 48 inches; grayish brown (2.5Y 5/2) silt loam; massive; very friable, slightly sticky and slightly plastic; common medium distinct yellowish brown (10YR 5/4) masses of iron accumulation and common medium faint gray (2.5Y 6/1) iron depletions; neutral; clear wavy boundary.

2Cg3'—48 to 72 inches; light brownish gray (2.5Y 6/2) loamy very fine sand; massive; very friable; few fine distinct yellowish brown (10YR 5/4) masses of iron accumulation and common medium faint gray (2.5Y 6/1) iron depletions; slightly effervescent, slightly alkaline.

Depth to bedrock is more than 60 inches. Rock fragments above a depth of 40 inches range from 0 to 5 percent and from 0 to 50 percent below 40 inches. Reaction ranges from extremely acid to neutral to a depth of about 30 inches and from extremely acid to slightly alkaline below 30 inches. Some subhorizon within the control section has a reaction of moderately acid to neutral. Some pedons have carbonates below a depth of 40 inches, and some pedons have buried horizons.

The O horizon, where present, has hue of 5YR to 10YR, value of 2 or 3 and chroma of 1 or 2. The horizon is less than 4 inches thick.

The A horizon, or Ap horizon where present, is neutral or has hue of 7.5YR to 2.5Y, value of 2 or 3 and chroma of 0 to 2. Texture is silt loam, very fine sandy loam, or their mucky analogues. Areas that have been drained and plowed are not mucky over a period of time. It has weak or moderate very fine to coarse granular structure. The A horizon is very friable or friable, nonsticky and nonplastic, or slightly sticky and slightly plastic.

The Cg horizon is neutral or has hue of 10YR to 5GY, value of 3 to 6 and chroma of 0 to 2. The upper part of the Cg horizon of most pedons has few or common, faint to prominent redox concentrations. Texture is silt loam, very fine sandy loam, or loamy very fine sand but below 40 inches ranges from silt loam to fine gravel. The Cg horizon is massive except the coarser textured Cg horizon, where present, may be single grain. Consistence is very friable or friable, nonsticky and nonplastic or slightly sticky and slightly plastic but ranges to loose where the Cg horizon is coarse textured.

Correlation Note: The MdA map unit is a taxadjunct to the Medomak series because the pedon qualifies as having a Mollic epipedon in the Ap horizon and is a Mollisols. The classification of the taxadjunct is Coarse-silty, mixed, superactive, frigid Fluvaquentic Endoaquolls. The classification of the Medomak series is Coarse-silty, mixed, supreactive, nonacid, frigid Fluvaquentic Humaquepts. This should not significantly affect use and management on a local basis for most purposes.

Monadnock Series

The Monadnock series consists of very deep, well drained soils on summits, shoulders, backslopes, and footslopes of glaciated hills and ridges, and on till plains. Monadnock soils formed in loamy sediments underlain by sandy or gravelly, friable glacial till. Slopes range from 3 to 60 percent.

Monadnock soils are associated on the landscape with Tunbridge, Sunapee, Tahawus, Adams, Colton, and Becket soils. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock. Sunapee soils are moderately well drained. Tahawus soils are sandy and very poorly drained. Adams soils are sandy and somewhat excessively drained. Colton soils are gravelly and excessively drained. Becket soils have a compact, very firm substratum.

Typical pedon of Monadnock fine sandy loam, 8 to 15 percent slopes, very bouldery, in the town of North Elba, in the road bank on the northeast side of McKenzie Pond Road (County Route 33), 1.4 miles northwest of NY Route 86, adjacent to fenced-in playing field; USGS Saranac Lake 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 18 minutes, 48 seconds N. and long. 74 degrees, 6 minutes, 0 seconds W.

Oe—0 to 2 inches, black (10YR 2/1) moderately decomposed (hemic) plant material; weak fine granular structure; very friable; many fine and very fine roots, common medium roots; 5 percent rock fragments (gravel and cobbles); very strongly acid; abrupt smooth boundary.

E—2 to 3 inches, brown (7.5YR 5/2) fine sandy loam; structureless; very friable; many fine and very fine roots, common medium roots; 5 percent rock fragments (gravel and cobbles); very strongly acid; abrupt smooth boundary.

Bs1—3 to 12 inches, brown (7.5YR 4/4) fine sandy loam; weak fine and medium subangular blocky structure; very friable; many fine and very fine roots, few medium roots; 10 percent rock fragments (gravel and cobbles); strongly acid; clear wavy boundary.

Bs2—12 to 19 inches, brown (7.5YR 5/4) fine sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and very fine roots, few medium roots; 10 percent rock fragments (gravel and cobbles); strongly acid; clear wavy boundary.

BC—19 to 30 inches, brown (10YR 5/3) fine sandy loam; massive; friable; common fine and very fine roots; 10 percent rock fragments (gravel and cobbles); strongly acid; gradual wavy boundary.

2C1—30 to 37 inches, brown (10YR 5/3) gravelly loamy sand; massive; friable; few fine and very fine roots; 15 percent gravel, 5 percent cobbles, 2 percent stones; strongly acid; gradual wavy boundary.

2C2—37 to 72 inches, grayish brown (10YR 5/2) gravelly sand; massive, with weak thin plate-like divisions in upper part; friable; few fine and very fine roots; 20 percent gravel, 5 percent cobbles, 2 percent stones; strongly acid.

The thickness of the mineral solum ranges from 15 to 30 inches. Rock fragments range from 0 to 30 percent in the mineral solum and from 5 to 60 percent in the substratum. Stones range from 0 to 20 percent in the surface layer, 0 to 15 percent in the subsoil, and 0 to 25 percent in the substratum. Cobbles range from 0 to 35 percent in the surface layer, 0 to 15 percent in the subsoil, and 0 to 20 percent in the substratum. Gravel ranges from 0 to 20 percent in the surface layer, 0 to 20 percent in the subsoil, and 0 to 45 percent in the substratum. Reaction ranges from extremely acid to moderately acid.

Some pedons have an 0 horizon that is neutral or has hue of 2.5YR to 10YR, value of 2 to 3 and chroma of 0 to 2. The horizon is highly, moderately, or slightly decomposed plant (fibric, hemic or sapric) material and is up to 5 inches thick.

The A horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is loam, very fine sandy loam, fine sandy loam, or sandy loam in the fine-earth fraction.

Some pedons have an Ap horizon that has hue of 10YR and value and chroma of 2 to 4.

The E horizon has hue of 5YR to 2.5Y, value of 4 to 7, and chroma of 1 or 2. Texture range is the same as the A horizon.

Some pedons have a Bhs horizon that has hue of 2.5YR to 7.5YR, value and chroma of 3 or less.

Some pedons have a Bh horizon that has hue of 2.5YR to 7.5YR, value and chroma of 4 or less.

The Bs horizon has hue of 2.5YR to 2.5Y, value of 3 to 6, and chroma of 3 to 8.

The Bs and Bhs horizons are dominantly fine sandy loam, but include loam and very fine sandy loam in the fine-earth fraction.

Some pedons have a BC horizon that has hue of 7.5YR to 5Y, value of 4 to 6, and chroma of 3 to 8. Texture is loam, fine sandy loam, sandy loam, loamy fine sand, or loamy sand in the fine-earth fraction. It is 0 to 15 inches thick.

Some pedons have a thin C horizon overlying the contrasting 2C horizon. Texture is fine sandy loam or sandy loam in the fine-earth fraction.

The 2C horizon has hue of 10YR to 5Y, value of 4 to 7, and chroma of 2 to 4. Texture is loamy coarse sand, loamy sand, or loamy fine sand in the fine-earth fraction. Less typically, some pedons may range to sand. Structure is weak thick platy or it is massive or single grain. Consistence ranges from loose to firm. Some pedons have lenses or pockets of sand.

Mooers Series

The Mooers series consists of very deep, moderately well drained sandy soils on deltas, outwash plains, outwash terraces, and high stream terraces in the Adirondack Upland. Mooers soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 5 percent.

Mooers soils are associated on the landscape with Champlain, Colton, Pyrities, Becket, Tunbridge, and Rumney soils. Champlain soils are somewhat excessively drained. Colton soils are gravelly and excessively drained. Pyrities and Becket soils are loamy and well drained. Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep over meta-igneous bedrock. Rumney soils are loamy and poorly drained.

Typical pedon of Mooers loamy fine sand, 0 to 3 percent slopes, in a wooded area, town of Lewis, 0.25 miles east on Steel Woods Road from junction with U.S. Route 9, then 120 feet south into woods; USGS Elizabethtown 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 14 minutes, 44 seconds N. and long. 73 degrees, 33 minutes, 48 seconds W.

Oe—0 to 1 inch, moderately decomposed plant (hemic) material; many fine and very fine roots; abrupt smooth boundary.

A—1 to 4 inches; very dark grayish brown (10YR 3/2) loamy fine sand, light brownish gray (10YR 6/2) dry; weak fine granular structure; very friable; many fine and very fine, common medium, and few coarse roots; strongly acid; clear wavy boundary.

Bw—4 to 16 inches; dark yellowish brown (10YR 4/6) loamy fine sand; weak medium subangular blocky structure; very friable; common fine and very fine, and few medium and coarse roots; moderately acid; gradual wavy boundary.

BC—16 to 22 inches; yellowish brown (10YR 5/4) fine sand; single grain; loose; common fine and very fine roots; 2 percent gravels and cobbles; moderately acid; gradual wavy boundary.

C1—22 to 42 inches; light yellowish brown (2.5Y 6/3) fine sand; single grain; loose; few very fine roots; 2 percent gravels and cobbles; common fine prominent strong

brown (7.5YR 5/6) soft masses of iron accumulation; slightly acid; clear wavy boundary.

C2—42 to 58 inches; light brownish gray (2.5Y 6/2) sand; single grain; loose; slightly acid; gradual wavy boundary.

C3—58 to 72 inches, grayish brown (2.5Y 5/2), sand; single grain; loose; common medium faint gray (2.5Y 5/1) depletions; slightly acid.

The thickness of the solum ranges from 22 to 55 inches. Depth to carbonates is greater than 50 inches. Redoximorphic features consisting of masses of iron accumulation occur between 18 and 30 inches of the soil surface. Redoximorphic depletions may also be present, but are restricted to below 40 inches from the soil surface. Depth to bedrock is greater than 60 inches. Rock fragments are typically absent, but may range up to 2 percent by volume in the lower subsoil and substratum. Unless the soil is limed, reaction ranges from strongly acid to slightly acid in the surface, and from moderately acid to slightly alkaline in the subsoil and substratum.

The Ap or A horizon, where present, has hue of 10YR, value of 3 or 4, and chroma of 2 or 3. Texture is sand, fine sand, loamy sand or loamy fine sand in the fine earth fraction. Structure is weak granular. Consistence is friable or very friable. The A horizon is 2 to 5 inches thick.

The Bw horizons have hue of 7.5YR or 10YR, value of 4 or 5, and chroma of 3 to 6. Faint to prominent redoximorphic concentrations occur between 18 and 30 inches. Texture is sand, fine sand, loamy sand or loamy fine sand in the fine earth fraction. Structure is weak or moderate subangular blocky or it is single grain. Consistence is very friable or loose.

The BC horizon has hue of 10YR or 2.5Y, value of 4 or 5 and chroma of 3 or 4. The horizon has typically has faint to prominent redoximorphic concentrations or depletions. Texture is sand or fine sand in the fine earth fraction. Structure is weak subangular blocky or it is single grain.

The C, 2C, and 3C, if present, horizons have hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 2 to 4. The horizons typically have faint to prominent redoximorphic concentrations or depletions. Texture is sand, fine sand or loamy fine sand in the fine earth fraction; but 2C horizons can have loamy very fine sand or silt loam textures below a depth of 40 inches. Structure is massive, with or without plate-like divisions, or single grain.

Mundalite Series

The Mundalite series consists of very deep, well drained soils on back slopes and upper footslopes of glaciated mountains and ridges in the Adirondack Upland. Mundalite soils formed in loamy sediments underlain by compact, sandy or loamy, very firm lodgment till. Slopes range from 3 to 60 percent.

Mundalite soils are associated on the landscape with Hogback, Rawsonville, Knob Lock, Ampersand, and Wilmington soils. Hogback soils have meta-igneous bedrock at 10 to 20 inches deep. Rawsonville soils have meta-igneous bedrock at 20 to 40 inches deep. Knob Lock soils are well drained to excessively drained, have meta-igneous bedrock from 2 to 20 inches deep, and are organic. The somewhat poorly drained Ampersand and poorly drained Wilmington soils are on the lower part of footslopes or on toeslopes.

Typical pedon of Mundalite fine sandy loam, in a map unit of Mundalite-Rawsonville complex, 15 to 35 percent slopes, very bouldery, in the town of Dannemora, about 1.9 mile south of the intersection with State Route 374 and 1.0 mile west of Chazy Lake Road; USGS Moffitsville topographic quadrangle; NAD 1927; lat. 44 degrees 43 minutes 27 seconds N. and long. 73 degrees 50 minutes 38 seconds W.

Oa—0 to 1 inch, black (5YR 2.5/1) highly decomposed plant (sapric) material consisting of decomposed roots and leaves.

E—1 to 3 inches, reddish gray (5YR 5/2) fine sandy loam; weak medium and fine subangular blocky structure; very friable; many fine and very fine, and few medium roots; 7 percent rock fragments; extremely acid; abrupt wavy boundary.

Bh—3 to 5 inches, dark reddish brown (5YR 2.5/2) fine sandy loam; weak medium and fine subangular blocky structure; very friable; many fine and very fine roots; strongly smeary; 7 percent rock fragments; very strongly acid; clear wavy boundary.

Bs1—5 to 14 inches, dark reddish brown (5YR 3/4) fine sandy loam; weak medium and fine subangular blocky structure; very friable; many fine and very fine, and few coarse and medium roots; many fine and very fine pores; moderately smeary; 10 percent gravel; strongly acid; clear wavy boundary.

Bs2—14 to 27 inches, dark reddish brown (5YR 3/4) cobbly fine sandy loam; weak coarse and medium subangular blocky structure; friable; common very fine and fine roots; common fine and very fine pores; moderately smeary; 15 percent rock fragments (including 5 percent gravel); very strongly acid; clear wavy boundary.

Cd1—27 to 37 inches, dark yellowish brown (10YR 3/4) very cobbly fine sandy loam; weak thick and very thick platy structure with loamy sand lenses between plates; very firm; few very fine roots in the upper part; common fine and very fine pores; 35 percent rock fragments

Cd2—37 to 72 inches, dark yellowish brown (10YR 4/4) very cobbly loamy sand; massive; very firm; common fine and very fine pores; few fine and medium distinct dark yellowish brown (10YR 4/6) soft masses of Fe accumulation in the matrix; 40 percent rock fragments (including 20 percent gravel); strongly acid.

The thickness of the solum and depth to dense basal till range from 25 to 40 inches. Rock fragments range from 0 to 25 percent in the solum and from 5 to 50 percent in the substratum. The spodic horizon typically is greater than 18 inches thick. Reaction ranges from extremely acid to moderately acid in the solum, and from very strongly acid to slightly acid in the substratum.

The O horizon consists of slightly to highly decomposed plant material. It is neutral or has hue of 5YR to 10YR, value of 2 or 2.5, and chroma of 1.

Some pedons have an A horizon that has a hue of 5YR to 10YR, value of 2 to 3, and chroma of 0 to 2, or the horizon is neutral. Texture of the fine earth fraction is loam, fine sandy loam or sandy loam. Structure is weak or moderate granular. Consistence is very friable.

The E horizon has hue of 2.5YR to 10YR, value of 4 or 5, and chroma of 0 to 3, or is the horizon neutral. Texture of the fine earth fraction is loam, fine sandy loam, or sandy loam. Structure is weak granular or subangular blocky. Consistence is very friable.

The Bh horizon has hue of 10R to 7.5YR, value of 2 to 3, and chroma of 0 to 2, or it is neutral. Texture of the fine earth fraction is loam, fine sandy loam, or sandy loam. Structure is weak or moderate granular, or subangular blocky. Consistence is very friable or friable.

Some pedons have a Bhs horizon up to 20 inches thick. The horizon has hue of 10R to 7.5YR, value of 3 or 4 and chroma of 2 or 3; or hue of 10YR with value and chroma of 2 or less. Texture of the fine earth fraction is loam, fine sandy loam, or sandy loam. Structure is weak prismatic or subangular blocky. Consistence is dominantly friable, but may also have firm masses.

The Bs horizon has hue of 10R to 7.5YR, value and chroma of 3 to 5. Texture of the fine earth fraction is loam, fine sandy loam, or sandy loam. Structure is weak subangular blocky. Consistence is dominantly friable, but some pedons have firm masses in the upper part.

Some pedons have a BC horizon that has hue of 7.5YR to 2.5Y, value of 4 or 5 and chroma of 2 to 6. Texture of the fine earth fraction is fine sandy loam, sandy loam,

loamy fine sand or loamy sand. Structure is subangular blocky or platy. Consistence is friable or firm.

The Cd horizon has hue of 10YR to 5Y, value 3 to 6, and chroma of 2 to 4. Texture of the fine earth fraction ranges from loamy sand to fine sandy loam. Structure is weak or moderate platy, or it is massive. Consistence is firm or very firm.

Naumburg Series

The Naumburg series consists of very deep, somewhat poorly drained soils on deltas, outwash plains, and outwash terraces. Naumburg soils formed in stratified, water deposited, sandy sediments. Slope ranges from 0 to 3 percent (fig. 43).

Naumburg soils are associated on the landscape with Adams, Croghan, Searsport, Fernlake, Monadnock, and Rumney soils. Adams soils are somewhat excessively drained. Croghan soils are moderately well drained. Searsport soils are very poorly drained. Fernlake soils are well drained. Monadnock soils are loamy over sandy and are well drained. Rumney soils are loamy and poorly drained.

Typical pedon of Naumburg loamy fine sand, 0 to 3 percent slopes, in a forested area, Town of North Elba, 2,800 feet south of Rt. 86, and 100 feet west of the old Penn Central Railroad bed; USGS Saranac Lake 15 topographic quadrangle; NAD 1927; lat. 44 degrees, 17 minutes, 50 seconds N. and long. 74 degrees, 06 minutes, 37 seconds W.

Oa—0 to 2 inches; black (N 2.5/0) highly decomposed (sapric) plant material; very friable; many very fine and fine, and common coarse roots; extremely acid; abrupt smooth boundary.

E—2 to 7 inches; gray (10YR 6/1) and (5YR 5/1) loamy fine sand; single grain; loose; few fine and medium roots; very strongly acid; abrupt wavy boundary.

Bhs—7 to 10 inches; dark reddish brown (5YR 3/3) loamy fine sand; weak fine subangular blocky structure; very friable; common fine and very fine roots; few fine prominent strong brown (7.5YR 5/6) masses of iron accumulation, and few medium faint brown (7.5YR 4/2) iron depletions; very strongly acid; abrupt wavy boundary.

Bs—10 to 18 inches; brown (7.5YR 5/3) loamy fine sand; single grain; loose; few fine and very fine roots; common coarse prominent yellowish red (5YR 5/6) masses of iron accumulation, and common medium faint grayish brown (10YR 5/2) iron depletions; very strongly acid; clear wavy boundary.

BC—18 to 31 inches; brown (10YR 5/3) fine sand, with lenses of loamy fine sand and loamy very fine sand up to 1 inch thick; single grain; loose; common coarse prominent strong brown (7.5YR 5/6) masses of iron accumulation and common medium faint dark grayish brown (10YR 4/2) iron depletions; very strongly acid; gradual wavy boundary.

Cg1—31 to 54 inches; grayish brown (10YR 5/2) sand, with thin lenses of black fine sand; single grain; loose; few fine prominent strong brown (7.5YR 5/8) masses of iron accumulation, and few fine faint gray (10YR 6/1) iron depletions; strongly acid; gradual wavy boundary.

Cg2—54 to 72 inches; gray (10YR 5/1) stratified coarse and medium sand; single grain; loose; 2 percent rock fragments (small gravel); strongly acid.

The thickness of the solum ranges from 18 to 42 inches. Depth to bedrock is more than 60 inches. Rock fragments are generally absent, but can range up to 5 percent by volume. Combined thickness of the Bhs and/or Bh and Bs horizons ranges from 7 to 32 inches thick.

The 0a horizon has hue of 5YR to 10YR, or is neutral, with value of 2 to 3, and chroma of 0 to 4. The organic materials are usually well decomposed plant materials derived predominantly from woody vegetation with a smaller amount from herbaceous.

Figure 43.—Soil profile of the Naumburg series from a hand dug pit, in the town of North Elba, in a spruce-fir forest. Note the excellent expression of spodosol development, a thick gray albic horizon and thick dark reddish brown spodic subsoil horizon, in this sandy soil. The mottled appearance of the subsoil indicates seasonal saturation and translocation of iron.

The rubbed fiber content is less than 15 percent of the volume. An Oe horizon, up to 2 inches thick, may overlie the Oa horizon in some pedons.

Some pedons have an A or Ap horizon that has hue of 5YR to 10YR, value of 2 to 5, and chroma of 1 to 4. Texture of the fine-earth fraction is fine sandy loam, sandy loam, loamy fine sand, or loamy sand. Ap horizons are up to 14 inches thick and have dry color values of 6. Reaction ranges from extremely acid to strongly acid unless limed.

The Eg or E horizon has hue of 5YR to 10YR, value of 5 to 7, and chroma of 1 to 3. Texture is similar to the A or Ap horizon. Consistence is friable to loose. Reaction ranges from extremely acid to strongly acid.

Some pedons have a Bh horizon that has hue of 2.5YR to 10YR, value of 2 or 3, and chroma of 1 to 3. Texture of the fine earth fraction ranges from loamy fine sand to sand. Structure is often weak granular or subangular blocky, but some pedons have single grain. Consistence ranges from very friable to loose, and some pedons have up to 35 percent firm or extremely firm parts. Reaction ranges from extremely acid to strongly acid.

The Bhs horizon, where present, has hue of 2.5YR to 10YR, and value and chroma of 2 or 3. The fine-earth fraction ranges from loamy fine sand to sand. Structure is often weak granular or subangular blocky. Reaction ranges from extremely acid to strongly acid.

The Bs horizon has hue of 5YR to 10YR, value of 3 to 5, and chroma of 3 to 6. Texture of the fine-earth fraction is loamy fine sand to sand. Consistence is very friable to loose, but can contain up to 20 percent firm or very firm parts. Reaction ranges from extremely acid to strongly acid.

The BC horizon has hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 2 to 6. Texture of the fine-earth fraction is loamy fine sand to sand. Consistence is very friable or loose, but some pedons have up to 20 percent firm or very firm parts. Reaction ranges from extremely acid to strongly acid.

The Cg or C horizon have hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Texture of the fine-earth fraction ranges from loamy fine sand to coarse sand. Reaction ranges from very strongly acid to slightly acid.

Nehasne Series

The Nehasne series consists of moderately deep, well drained soils on summits, shoulders, and backslopes of glaciated hills and ridges in the eastern foothills of the Adirondack High Peaks Region. Nehasne soils formed in loamy sediments deposited by glacial ice, and are underlain by massive marble bedrock. Slopes range from 8 to 35 percent.

Nehasne soils are associated on the landscape with Pyrities, Kalurah, Malone, Typic Endoaquolls, Tunbridge, and Monadnock soils. Pyrities soils are very deep. Kalurah soils are very deep and moderately well drained. Malone soils are very deep and somewhat poorly drained. Typic Endoaquolls soils are very deep and poorly drained. Tunbridge soils are more acid and are underlain by meta-igneous bedrock. Monadnock soils are loamy over sandy or gravelly, very deep, and are more acid.

Typical Pedon of Nehasne loam, in a map unit of Pyrities-Nehasne complex, 15 to 25 percent slopes, rocky, in an idle pasture, town of Crown Point, 100 feet south of a point on North Road that is 3,000 feet west of junction of North Road and Whitehead Road; USGS Crown Point, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 56 minutes 09 seconds N. and long. 73 degrees 33 minutes 07 seconds W.

Ap—0 to 6 inches; very dark grayish brown (10YR 3/2) loam; pale brown (10YR 6/3) dry; moderate fine and medium granular structure; friable; many very fine and fine roots; 7 percent rock fragments; slightly acid; abrupt smooth boundary.

Bw1—6 to 13 inches; dark yellowish brown (10YR 4/4) loam; weak fine and medium subangular blocky structure; friable; common very fine and fine roots; common fine vesicular and tubular pores; 10 percent rock fragments; neutral; clear wavy boundary.

Bw2—13 to 20 inches; dark yellowish brown (10YR 4/6) fine sandy loam; weak fine and medium subangular blocky structure; friable; few very fine and fine roots; few fine vesicular and common fine tubular pores; 10 percent rock fragments; neutral; clear wavy boundary.

C—20 to 25 inches; dark brown (10YR 3/3) gravelly fine sandy loam; massive with plate-like divisions; firm; few fine roots; common fine tubular pores; 20 percent rock fragments; neutral; abrupt irregular boundary.

R—25 inches; marble bedrock.

The thickness of the solum and depth to bedrock range from 20 to 40 inches. Rock fragments, mostly gravel and cobbles, range from 5 to 25 percent in the upper part of the mineral solum and from 20 to 45 percent in the BC horizon and in the C horizon, where present.

The A horizon has hue of 10YR or 7.5YR, value of 2 to 3, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or loam in the fine-earth fraction. Structure is weak or moderate granular. Consistence is friable or very friable. Reaction is moderately acid or slightly acid.

The Bw horizon has hue of 10YR or 7.5YR, value of 3 or 4, and chroma of 2 to 6. Texture is commonly fine sandy loam and less commonly loam in the fine-earth fraction. Structure is weak or moderate subangular blocky. Consistence is friable or very friable. Reaction is slightly acid or neutral.

The BC horizon has hue of 10YR, value of 3 to 5, and chroma of 3. Texture is

loam, fine sandy loam, or sandy loam in the fine-earth fraction. Structure is weak or moderate subangular blocky, or it is massive. Consistence is friable or very friable. Reaction is neutral or slightly alkaline.

Some pedons have a C horizon with hue of 10YR, value of 3 to 5, chroma of 3. Texture is loam, fine sandy loam, or sandy loam in the fine-earth fraction. Structure is massive. Consistence is friable or firm. Reaction is neutral or slightly alkaline.

Nellis Series

The Nellis series consists of very deep, well drained soils on summits, shoulders, and backslopes of glaciated ridges and on till plains in the Champlain Valley. Nellis soils formed in loamy sediments underlain by firm, loamy, calcareous till. Slopes range from 3 to 25 percent (fig. 44).

Nellis soils are associated on the landscape with Amenia, Bombay, Massena, Kingsbury, Covington, Cayuga, Claverack, and Howard soils. Amenia and Bombay soils are moderately well drained. Massena soils are somewhat poorly drained. Kingsbury and Covington soils are clayey and are somewhat poorly drained and

Figure 44.—Soil profile of the Nellis series from a backhoe test pit, in the town of Essex, in a hay field. This soil on gently sloping landforms is considered to be prime farmland. It has good native fertility, tilth, drainage, and available water. This soil also has few if any limitations for residential development.

poorly drained respectively. Cayuga soils are clayey over loamy and are moderately well drained. Claverack soils are sandy over clayey and are moderately well drained. Howard soils are gravelly and are well drained to excessively drained.

Typical pedon of Nellis fine sandy loam, 8 to 15 percent slopes, in a hay field, in the town of Essex, 500 feet east of the point on Clark Road that is located 500 feet south of the junction of Clark and Cross Roads; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 15 minutes 47 seconds N. and long. 73 degrees 23 minutes 01 seconds W.

Ap—0 to 9 inches, dark brown (10YR 3/3) fine sandy loam, pale brown (10YR 6/3) dry; moderate fine and medium granular structure; very friable; many very fine and fine and few medium roots; common fine and few medium tubular pores, and many fine vesicular pores; 5 percent rock fragments; neutral; abrupt smooth boundary.

Bw1—9 to 16 inches, dark yellowish brown (10YR 4/4) fine sandy loam; weak fine and medium subangular blocky structure; very friable; many fine and very fine and few medium roots; common fine and few medium tubular and many fine vesicular pores; 5 percent rock fragments; neutral; clear wavy boundary.

Bw2—16 to 21 inches, brown (10YR 4/3) fine sandy loam; moderate fine and medium subangular blocky structure; very friable; common very fine and fine roots; common fine and few medium tubular pores, and many fine vesicular pores; 5 percent rock fragments; neutral; clear wavy boundary.

BC1—21 to 26 inches, brown (10YR 5/3) fine sandy loam; massive with thin and medium plate-like divisions; friable; common very fine and fine roots; common fine vesicular and few fine tubular pores; 6 percent rock fragments; neutral; clear smooth boundary.

BC2—26 to 37 inches, 80 percent brown (10YR 5/3), 10 percent yellowish brown (10YR 5/6), and 10 percent brown (7.5YR 4/2) fine sandy loam; massive with medium and thick plate-like divisions; firm; few very fine and fine roots; few fine tubular and common fine vesicular pores; 8 percent rock fragments; few fine faint brown (7.5YR 5/4) soft masses of iron accumulation; neutral; gradual wavy boundary.

C—37 to 60 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive with plate like divisions; firm; few very fine and fine roots; few fine tubular and few fine vesicular pores; 9 percent rock fragments; moderately alkaline, violently effervescent; gradual wavy boundary.

Cd—60 to 80 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive; very firm; 13 percent rock fragments; moderately alkaline, violently effervescent.

The thickness of mineral solum ranges from 15 to 37 inches and depth to carbonates range from 15 to 38 inches. Depth to bedrock is greater than 60 inches. Rock fragments range from 3 to 35 percent by volume in the A horizon, 5 to 35 percent in the B horizon, and 5 to 50 percent in the C horizon. Reaction ranges from moderately acid to neutral in the upper part of the mineral solum, moderately acid to slightly alkaline in the lower part of the solum and neutral to moderately alkaline in the substratum.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 or 4, and chroma of 2 to 4 moist, and value of 4 to 6, chroma of 2 to 5 dry. It ranges from fine sandy loam to silt loam in the fine earth fraction. It has weak or moderate granular structure. Consistence is very friable or friable. Undisturbed areas have an A horizon 2 to 6 inches thick.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 4. The B horizon ranges from fine sandy loam to silt loam in the fine earth fraction. It has weak or moderate, fine or medium subangular blocky structure except some subhorizons may be massive. Consistence is very friable or friable. Faint redoximorphic features are at the contact between the B and C horizons in some pedons.

The BC or CB horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 6. Faint redoximorphic features are in some pedons. Texture ranges from fine sandy

loam to silt loam in the fine earth fraction. Structure is weak or moderate subangular blocky or it is massive with or without plate-like divisions. Consistence is friable or firm.

The C horizon has hue of 10YR to 5Y, value of 3 to 7, and chroma of 2 to 6. Chroma 2 is a result of parent material or lithologic origin rather than redoximorphic depletion. Texture is sandy loam, fine sandy loam or loam in the fine earth fraction. Consistence is friable or firm. The C horizon is calcareous and the carbonates are mostly $CaCO_3$. Some pedons have Cd horizons with firm or very firm consistence at 60 inches or below.

Niagara Series

The Niagara series consists of very deep, somewhat poorly drained soils on lacustrine terraces and lake plains in the Champlain Valley. Niagara soils formed in silty clay sediments deposited in still water. Slopes range from 0 to 8 percent.

Niagara soils are associated on the landscape with Dunkirk, Collamer, Kingsbury, Covington, Tonawanda, Farmington, and Amenia soils. Dunkirk soils are well drained. Collamer soils are moderately well drained. Kingsbury soils have higher clay content. Covington soils have higher clay content and are poorly drained. Tonawanda soils have less clay. Farmington soils are loamy, well drained, and are 10 to 20 inches deep to limestone bedrock. Amenia soils are loamy and moderately well drained.

Typical pedon of Niagara silt loam, 0 to 3 percent slopes, in the town of Chesterfield, 1,500 feet east of a point on U.S. Route 9 that is 1,920 feet north of the junction of U.S. Route 9 and Robare Road, in a pasture; USGS Willsboro, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 28 minutes 36 seconds N. and long. 73 degrees 28 minutes 50 seconds W.

Ap—0 to 9 inches, very dark grayish brown (10YR 3/2) silt loam; light brownish gray (10YR 6/2) dry; weak medium and coarse subangular blocky parting to weak medium and fine granular structure; friable; non-sticky, slightly plastic; many very fine roots; neutral; abrupt smooth boundary.

E—9 to 12 inches, brown (10YR 5/3) silt loam; weak thick and medium platy parting to weak fine subangular blocky structure; friable; non-sticky, non-plastic; many very fine roots; few very fine tubular pores; light brownish gray (10YR 6/2) ped faces; common medium and fine distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral; clear smooth boundary.

BE—12 to 18 inches, brown (10YR 5/3) silt loam; moderate fine subangular blocky structure; friable; slightly sticky and slightly plastic; common very fine roots; few very fine tubular pores; few thin clay films on ped faces, grayish brown (10YR 5/2) ped faces; many fine and medium distinct yellowish brown (10YR 5/6) and few fine distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation; neutral; clear wavy boundary.

Bt—18 to 35 inches, brown (10YR 5/3) silty clay loam; moderate coarse prismatic structure parting to moderate thick platy structure; firm, slightly sticky and plastic; common very fine roots along prism faces; few fine tubular pores; common thin clay films on ped faces and in pore linings; grayish brown (10YR 5/2) prism faces with 5 to 10 mm thick yellowish brown (10YR 5/6) borders; 1 percent rock fragments; common medium and fine distinct yellowish brown (10YR 5/6) and few fine distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation, few fine faint grayish brown (10YR 5/2) iron depletions; neutral; clear smooth boundary.

C1—35 to 48 inches, brown (10YR 4/3) silty clay loam; weak coarse prismatic parting to weak thick platy structure; firm; slightly sticky and plastic; few very fine tubular pores; grayish brown (10YR 5/2) prism faces; 3 percent rock fragments; few fine faint light brownish gray (10YR 6/2) iron depletions, common fine distinct dark yellowish brown (10YR 4/6) masses of iron accumulation; slightly alkaline, slightly effervescent; clear smooth boundary.

C2—48 to 72 inches, brown (10YR 4/3) silty clay loam; moderate coarse prismatic parting to weak thick platy structure; firm; slightly sticky and plastic; few very fine and fine tubular pores; grayish brown (10YR 5/2) prism faces; 5 percent rock fragments; common medium and coarse faint brown (10YR 5/3) and common medium and fine distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation; slightly alkaline, slightly effervescent.

The thickness of the solum ranges from 20 to 40 inches. Depth to bedrock is greater than 60 inches. Depth to carbonates ranges from 20 to 50 inches. Rock fragments are generally absent, but can range up to 5 percent by volume. In some pedons that are underlain with till deposits at depths greater than 40 inches, rock fragment content ranges up to 35 percent in the substratum.

The Ap or A horizon has hue of 10YR or 2.5Y, value of 3 or 4, and chroma of 2 or 3, and value of 6 or 7 dry. Texture of the fine-earth fraction is fine sandy loam, very fine sandy loam, loam, or silt loam. Consistence is friable or very friable. Reaction ranges from strongly acid to neutral. Thickness of the Ap horizon ranges from 4 to 10 inches.

The E or Eg horizon has hue of 7.5YR to 2.5Y, value of 5 or 6, and chroma of 2 to 4. Texture of the fine-earth fraction ranges from fine sandy loam to silt loam. The E horizon is massive, or has weak fine subangular blocky, or thin to thick platy structure. Consistence is friable or very friable. Reaction ranges from strongly acid to neutral.

Some pedons have a BE or BA horizon with colors and textures similar to the A, E, and B horizons.

The Bt horizon has hue of 5YR to 2.5Y, value of 4 or 5, and chroma of 2 to 4 with faint to prominent redoximorphic features. Texture of the fine-earth fraction is very fine sandy loam, silt loam, or silty clay loam with thin subhorizons of finer or coarser textures in many pedons. Structure is subangular or angular blocky with patchy clay skins on faces of peds. Some pedons have coarse or very coarse prismatic or thick platy structure. Consistence is friable or firm. Reaction ranges from moderately acid through slightly alkaline.

Some pedons have a BC horizon up to 12 inches thick with colors and texture similar to the B horizon.

The C horizon has hue of 5YR to 5Y or is neutral, and has value of 3 to 6, and chroma of 0 to 6. Texture of the fine-earth fraction is dominantly very fine sandy loam, silt loam or silty clay loam, but has stratified layers ranging from fine sand to clay. Reaction ranges from neutral to moderately alkaline. Some pedons underlain with till have a 2C horizon.

Nicholville Series

The Nicholville series consists of very deep, moderately well drained soils on lacustrine terraces in intermontane valleys of the Adirondack Uplands. Nicholville soils formed in silt and very fine sand sediments deposited by wind or in still water. Slopes range from 3 to 8 percent.

Nicholville soils are associated on the landscape with Roundabout, Hailesboro, Becket, Fernlake, and Champlain soils. Roundabout soils are somewhat poorly drained. Hailesboro soils are more clayey and are somewhat poorly drained. Becket soils are loamy and well drained. Fernlake soils are sandy and well drained. Champlain soils are sandy and somewhat excessively drained.

Typical pedon of Nicholville silt loam, 3 to 8 percent slopes, in a wooded area, 0.45 miles south on Trout Pond Road from the intersection with Green Street, and 0.32 miles due east into woods; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 27 minutes 03 seconds N. and long. 73 degrees 34 minutes 24 seconds W.

Oi—0 to 1 inch; slightly decomposed leaf, needle and twig material.

Ap—1 to 6 inches; very dark grayish brown (10YR 3/2) silt loam, light brownish gray (10YR 6/2) dry; weak fine and medium granular structure; very friable; many very fine and fine, common medium and few coarse roots; strongly acid; abrupt smooth boundary.

E—6 to 7 inches; grayish brown (10YR 5/2) silt loam; weak fine subangular blocky parting to weak fine granular structure; very friable; common fine and very fine roots; strongly acid; abrupt smooth boundary.

Bs—7 to 12 inches; brown (7.5YR 5/4) silt loam; weak fine subangular blocky structure; friable; common fine and very fine roots; common very fine tubular pores; strongly acid; clear wavy boundary.

BC—12 to 20 inches; brown (10YR 5/3) silt loam; weak medium and fine subangular blocky structure; friable; common fine and very fine roots; common very fine tubular pores; few fine distinct yellowish brown (10YR 5/6) masses of iron accumulation, common brown (7.5YR 5/4) stains on ped faces, and common medium distinct gray (10YR 6/1) iron depletions in lower part; moderately acid; clear wavy boundary.

C1—20 to 25 inches; grayish brown (10YR 5/2), and light brownish gray (10YR 6/2) very fine sandy loam; massive with thin plate-like divisions; friable; few very fine roots; common fine tubular and common fine and medium vesicular pores; moderately acid; clear wavy boundary.

C2—25 to 38 inches; grayish brown (10YR 5/2) silt loam; massive; friable; few fine tubular and common fine and medium vesicular pores; common faint distinct gray (10YR 6/1) iron depletions; moderately acid; gradual wavy boundary.

C3—38 to 54 inches; grayish brown (2.5Y 5/2) silt loam; massive; friable; few fine tubular and vesicular pores; common fine prominent strong brown (7.5YR 5/6) and yellowish brown (10YR 5/6) masses of iron accumulation; slightly acid; clear wavy boundary.

C4—54 to 72 inches; grayish brown (2.5Y 5/2) very fine sandy loam; massive; very friable; few very fine tubular pores; few fine prominent yellowish brown (10YR 5/6) masses of iron accumulation; neutral.

The thickness of the solum ranges from 12 to 38 inches. Depth to bedrock is greater than 60 inches. Depth to contrasting deposits is greater than 30 inches. Rock fragments, mostly gravel, range from 0 to 10 percent by volume throughout the soil. Redoximorphic features are within a depth of 30 inches.

The A or Ap horizon, where present, has hue of 7.5YR or 10YR, value of 3 or 4, and chroma of 2 or 3. Texture is silt loam or very fine sandy loam. Consistence is friable or very friable. Reaction ranges from extremely acid to moderately acid, unless limed.

In undisturbed areas, the soil typically has an O horizon, an E horizon, and may also have a Bhs or Bh horizon. These horizons are usually destroyed by plowing.

The E horizon, where present, has hue of 5YR to 10YR, value of 3 to 7, and chroma of 1 to 4. Texture is silt loam or very fine sandy loam. Consistence is friable or very friable. Reaction ranges from extremely acid to moderately acid, unless limed.

The Bhs horizon where present, has hue of 2.5YR to 7.5YR, and value and chroma of 3 or less. The Bh horizon where present, has hue of 2.5YR to 7.5YR, and value and chroma of 4 or less. Texture ranges from loamy very fine sand to silt loam. Consistence is very friable to firm. Reaction ranges from very strongly acid to moderately acid.

The Bs horizons have hue of 5YR or 7.5YR, value of 3 to 6, and chroma of 2 to 4. Texture ranges from loamy very fine sand to silt loam. Consistence is very friable to firm. Reaction ranges from very strongly acid to moderately acid.

The BC horizon, where present, has hue of 10YR to 5Y, value of 4 or 5 and chroma of 3 or 4. It has distinct or prominent redoximorphic features. Texture ranges from very fine sand to silt loam. Reaction ranges from very strongly acid to moderately acid.

The 2C or C horizon has hue of 10YR to 5Y, value of 4 to 6 and chroma of 2 to 4. Texture is very fine sand to silt loam. The horizon is single grain, massive, or has weak platy divisions associated with depositional layers. Consistence is very friable to firm. Reaction ranges from very strongly acid to neutral.

Occum Series

The Occum series consists of very deep, well drained soils on flood plains in the Champlain Valley. Occum soils formed in loamy sediments deposited by floodwaters. Slopes range from 0 to 3 percent (fig. 45).

Occum soils are associated on the landscape with Pootatuck, Rippowam, Windsor, Vergennes, Charlton, and Chatfield soils. Pootatuck soils are moderately well drained. Rippowam soils are poorly drained. Windsor soils are sandy and are excessively drained. Vergennes soils are clayey and are moderately well drained. Charlton soils have higher rock fragment contents throughout the soil. Chatfield soils are 20 to 40 inches deep to meta-igneous bedrock.

Typical pedon of Occum fine sandy loam, 0 to 3 percent slopes, in a corn field, in the town of Essex, adjacent to Boquet River, 200 feet west of a point on Anger Hill Road that is 1 mile south of the junction of Anger Hill Road and Whallons Bay Road. USGS Willsboro 15 minute topographic quadrangle; 44 degrees 15 minutes 02 seconds north latitude, 73 degrees 24 minutes 26 seconds west longitude; NAD 1927.

Ap—0 to 9 inches, dark yellowish brown (10YR 3/4) fine sandy loam; light yellowish brown (10YR 6/4) dry; weak fine granular structure; very friable; many very fine roots; moderately acid; clear smooth boundary.

Bw1—9 to 21 inches, dark yellowish brown (10YR 3/4) fine sandy loam; weak medium subangular blocky structure; very friable; common very fine roots; slightly acid; abrupt smooth boundary.

Bw2—21 to 30 inches, dark brown (10YR 3/3) fine sandy loam; weak medium subangular blocky structure; very friable; few very fine roots; slightly acid; abrupt smooth boundary.

C1—30 to 36 inches, light olive brown (2.5Y 5/4) stratified loamy fine sand, loamy sand, sand, and fine sandy loam; single grain; loose; slightly acid; abrupt smooth boundary.

C2—36 to 72 inches, dark grayish brown (2.5Y 4/2) stratified sand, loamy sand, loamy fine sand, and fine sandy loam; single grain; loose; slightly acid.

The thickness of the solum and depth to the coarse-textured substratum range from 20 to 40 inches. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 60 percent in the substratum. Some pedons have up to 10 percent cobbles in the substratum. Unless limed, reaction ranges from very strongly acid to slightly acid.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. Texture is very fine sandy loam, fine sandy loam, or sandy loam. The horizon has weak or moderate granular structure and is friable or very friable.

The Bw horizon has hue of 7.5YR to 2.5Y, value of 3 to 8, and chroma of 3 to 6. Texture is commonly fine sandy loam or sandy loam, but the range includes very fine sandy loam or loam in the upper part. Some pedons have thin strata of loam, very fine sandy loam, or silt loam. The Bw horizon has granular or subangular blocky structure, or it is massive. Consistence is friable or very friable. Some pedons have thin Ab horizons.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 7, and chroma of 2 to 6. Some pedons have redoximorphic features below a depth of 4 feet. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are thin loamy and/or extremely gravelly strata. Also, some pedons have a loamy C horizon layer just below the Bw horizon. The C horizon is single

Figure 45.—Soil profile of the Occum series from a river bank cut, in the town of Essex, on the edge of a hay field. Note the banded light and dark alluvial depositional layers. Darker areas indicate stable periods and topsoil development. Occum is a class 1 agricultural soil and prime farmland. Regrettably, it is of small extent in the county.

grain and loose in the sandy part. The loamy part is typically massive and friable. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of the alluvial deposits.

Ondawa Series

The Ondawa series consists of very deep, well drained soils on flood plains in intermontane valleys of the Adirondack Upland. Ondawa soils formed in loamy sediments deposited by floodwaters. Slopes range from 0 to 3 percent.

Ondawa soils are associated on the landscape with Podunk, Rumney, Burnt Vly, Adams, Colton, Monadnock, Becket, and Tunbridge soils. Podunk soils are moderately well drained. Rumney soils are poorly drained. Burnt Vly soils are mucky and very poorly drained. Adams soils are sandy and somewhat excessively drained. Colton soils are gravelly and excessively drained. Monadnock soils are loamy over sandy or

gravelly. Becket soils have a compact, very firm substratum. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock.

Typical pedon of Ondawa sandy loam, 0 to 3 percent slopes, in a cropped field, in the town of North Elba, 500 feet west of County Road 21, about .8 miles northeast of junction with New York Route 73; USGS Lake Placid, NY 15 minute topographic quadrangle; NAD 1927; 44 degrees 15 minutes 52 seconds N. and long. 73 degrees 57 minutes 16 seconds W.

Ap—0 to 9 inches, dark grayish brown (10YR 4/2) sandy loam; weak medium granular structure; friable; many fine roots; strongly acid; abrupt smooth boundary.

Bw1—9 to 21 inches, brown (10YR 4/3) sandy loam; weak medium granular structure; very friable; common to many roots; strongly acid; gradual smooth boundary.

Bw2—21 to 34 inches, brown (10YR 5/3) fine sandy loam; weak fine granular structure; very friable; few roots in upper part; strongly acid; clear smooth boundary.

C—34 to 72 inches, pale brown (10YR 6/3) loamy fine sand; single grain; loose; 5 percent fine gravel; strongly acid.

The thickness of the solum and depth to the coarse-textured substratum ranges from 20 to 40 inches. Depth to bedrock is more than 60 inches. Clay content is less than 10 percent, and gravel ranges from 0 to 15 percent in the solum and from 0 to 40 percent in the substratum. Reaction ranges from very strongly acid to slightly acid throughout, unless limed. Some pedons have buried horizons.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. Dry value is 6 or more. Texture is fine sandy loam, sandy loam, or loam. The Ap horizon has weak or moderate, very fine to medium granular structure. Consistence is very friable or friable.

The Bw horizon has hue of 10YR or 2.5Y, with value of 3 to 8, and chroma of 2 to 8. Texture is fine sandy loam, sandy loam, or loam. The Bw horizon has weak or moderate, very fine, fine or medium granular or weak fine and medium subangular blocky structure. Consistence is very friable or friable.

The C horizon has hue of 10YR to 5Y, value of 3 to 7, and chroma of 2 to 6. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine earth fraction. Included in some pedons are loamy and/or extremely gravelly strata. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of the alluvial deposits. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and friable.

Pittsfield Series

The Pittsfield series consists of very deep, well drained soils on summits, shoulders, backslopes, and footslopes of hills and ridges and on till plains in the Champlain Valley. Pittsfield soils formed in loamy sediments, underlain by friable, calcareous glacial till. Slopes range from 3 to 60 percent.

Pittsfield soils are associated on the landscape with Georgia, Massena, Chatfield, Hollis, Howard, Kingsbury, and Cayuga soils. Georgia soils are moderately well drained. Massena soils are somewhat poorly drained. Chatfield and Hollis soils are 20 to 40 inches and 10 to 20 inches deep respectively to meta-igneous bedrock. Howard soils are gravelly. Kingsbury soils are clayey and somewhat poorly drained. Cayuga soils are clayey over loamy and moderately well drained.

Typical pedon of Pittsfield loam, in a map unit of Pittsfield-Chatfield complex, 3 to 8 percent slopes, rocky, very stony, in the town of Chesterfield, 400 feet northwest of B. Brinton's barn, at the very end of Brinton Road, in a hay field; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 29 minutes 49 seconds N. and long. 73 degrees 25 minutes 45 seconds W.

Ap—0 to 8 inches, dark brown (10YR 3/3) loam, pale brown (10YR 6/3) dry; weak fine and medium granular structure; very friable; many very fine and fine roots; 10 percent rock fragments; very strongly acid; abrupt smooth boundary.

EB—8 to 10 inches, yellowish brown (10YR 5/4) fine sandy loam; weak medium subangular blocky structure; friable; many fine and very fine roots; 10 percent rock fragments; strongly acid; clear broken boundary.

Bw1—10 to 20 inches, yellowish brown (10YR 5/6) gravelly fine sandy loam; weak medium subangular blocky structure; friable; many fine and common medium and coarse roots; 15 percent rock fragments; moderately acid; clear wavy boundary.

Bw2—20 to 24 inches, dark yellowish brown (10YR 4/4) loam; weak medium subangular blocky structure; friable; common very fine and fine, and few medium and coarse roots; 10 percent rock fragments; moderately acid; clear wavy boundary.

Bw3—24 to 30 inches, brown (10YR 4/3) gravelly loam; weak medium and coarse subangular blocky structure; friable; common fine and very fine roots; 15 percent rock fragments; slightly acid; clear irregular boundary.

BC—30 to 45 inches, brown (10YR 4/3) gravelly fine sandy loam; weak thick platy parting to weak coarse and medium subangular blocky structure; friable; common very fine and fine roots; 20 percent rock fragments; slightly acid; clear smooth boundary.

C1—45 to 59 inches, light olive brown (2.5Y 5/4) gravelly fine sandy loam; massive with medium plate-like divisions; friable; common very fine and fine roots in upper part; 20 percent rock fragments; slightly alkaline, slightly effervescent; clear smooth boundary.

C2—59 to 70 inches, grayish brown (2.5Y 5/2) gravelly fine sandy loam; massive with medium plate-like divisions; firm; 15 percent rock fragments; moderately alkaline, violently effervescent.

The thickness of solum ranges from 20 to 45 inches. Bedrock is deeper than 65 inches. Rock fragments consist primarily of schist and weathered limestone. Rock fragments range from 0 to 20 percent in the A horizon and from 5 to 34 percent in the B and C horizons. Cobbles typically occupy 0 to 15 percent of the A, 0 to 10 percent of the B and 0 to 15 percent of the C horizon. Gravel content typically ranges from 0 to 15 percent in the A, from 5 to 15 percent in the B and from 5 to 20 percent in the C horizon. Gravel content in the C horizon can range up to 34 percent but the horizon has less than 35 percent rock fragments. Depth to carbonates ranges from 40 to 72 inches. Reaction ranges from very strongly acid to moderately acid in the A; commonly moderately acid to neutral in the Ap but the range includes very strongly acid; from strongly acid to neutral in the upper part of the B horizon and from moderately acid to neutral in the lower part of the B horizon; and from moderately acid to moderately alkaline in the C horizon. Reaction is less acid than strongly acid and base saturation is more than 60 percent in some part of the 10 to 30 inch depth.

The Ap and A have a hue of 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is loam or fine sandy loam. The horizons have weak or moderate fine and medium granular structure and friable or very friable consistence.

Some pedons have a thin E, EB, or BE horizon below the A horizon. It has hue of 10YR or 2.5Y, value of 4 to 6, and chroma of 1 to 4. Texture is loam or fine sandy loam. Structure is weak fine or medium granular, or weak fine and medium subangular blocky and consistence is friable or very friable.

The Bw horizons have hue of 5YR to 2.5Y, values of 4 or 5 and chroma of 2 to 6. Texture is fine sandy loam or loam. Structure is weak fine or medium granular, or commonly weak fine and medium subangular blocky but the range includes weak coarse subangular blocky. Consistence is friable or very friable.

The BC horizon has hue of 10YR or 2.5Y, value of 4 or 5, and chroma of 2 to 4. Texture is sandy loam, fine sandy loam, loam or gravelly or channery analogs. It is

massive or has weak thick or very thick platy structure. Chroma of 2 is lithochromic and not related to wetness. Some pedons have a few high chroma redoximorphic concentrations in the lower part of the BC horizon.

The C horizons have hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 to 4. Texture is loam, fine sandy loam, sandy loam, or their gravelly or channery analogs. Pockets or lenses of loamy sand or sand are in some pedons. The C horizon is massive or appears in the form of non-pedogenically derived plates. It is friable or firm.

Pleasant Lake Series

The Pleasant Lake series consists of very deep, very poorly drained soils on broad flood plains and upland depressions of glaciated hills and ridges, and in depressions on deltas and outwash plains in the Adirondack Upland. Pleasant Lake soils formed in deep, saturated, decomposing plant material. Slopes range from 0 to 2 percent.

Pleasant Lake soils are associated on the landscape with Burnt Vly, Rumney, Adams, Monadnock, Becket, Adirondack, and Tahawus soils. Burnt Vly soils are 16 to 51 inches deep to sandy sediments. Rumney soils are loamy and poorly drained. Adams soils are sandy and somewhat excessively drained. Monadnock soils are loamy over sandy or gravelly and well drained. Becket soils are loamy and well drained. Adirondack soils are loamy and somewhat poorly drained. Tahawus soils are sandy.

Typical pedon of Pleasant Lake peat, in a map unit of Pleasant Lake-Burnt Vly complex, 0 to 2 percent slopes, in the town of North Hudson, 0.8 mile southeast on logging road from northernmost stream feeding Boreas Ponds, then 170 feet Southwest from logging road, in a stand of black spruce; USGS Mount Marcy, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 2 minutes, 17 seconds N. and long. 73 degrees, 54 minutes, 17 seconds W.

Oi—0 to 4 inches, black (10YR 2/1) broken face and mixed brown (10YR 4/3) and very dark grayish brown (10YR 3/2) rubbed peat (fibric material); 90 percent unrubbed fiber and 75 percent rubbed fiber; massive; very friable; extremely acid; abrupt smooth boundary.

Oa—4 to 5 inches, black (10YR 2/1) broken face and black (5YR 2.5/1) rubbed muck (sapric material); 25 percent unrubbed fiber and 5 percent rubbed fiber; massive; very friable; few fine roots; extremely acid; abrupt smooth boundary.

Oe—5 to 9 inches, reddish brown (5YR 4/3) broken face and dark reddish brown (5YR 3/2) rubbed mucky peat (hemic material); 40 percent unrubbed fiber and 20 percent rubbed fiber; massive; very friable; few fine roots; extremely acid; clear wavy boundary.

O’a1—9 to 31 inches, black (5YR 2.5/1) broken face and very dark gray (5YR 3/1) rubbed muck (sapric material); 10 percent unrubbed fiber and 2 percent rubbed fiber; weak fine subangular blocky structure; very friable; 10 percent woody fragments; extremely acid; clear wavy boundary.

O’a2—31 to 44 inches, dark reddish brown (5YR 3/2) broken face and rubbed muck (sapric material); 25 percent unrubbed fiber and 10 percent rubbed fiber; weak fine subangular blocky structure; very friable; extremely acid; diffuse wavy boundary.

O’e—44 to 53 inches, very dark gray (5YR 3/1) broken face and dark reddish brown (5YR 3/2) rubbed mucky peat (hemic material); 30 percent unrubbed fiber and 20 percent rubbed fiber; massive; very friable; extremely acid; abrupt smooth boundary.

O’i—53 to 66 inches, dark reddish brown (5YR 3/2 and 3/3) broken face and dark reddish brown (5YR 3/2) rubbed peat (fibric material); 75 percent unrubbed fiber and 60 percent rubbed fiber; massive; very friable; extremely acid.

The combined thickness of the organic layers exceeds 51 inches.

The layers in the surface tier consist dominantly of hemic materials, but in some

pedons they are composed of fibric or sapric material. Fibric horizons are dominantly sphagnum moss and have hue of 5YR to 10YR, value of 3 to 5, and chroma of 2 to 6. These layers are derived from herbaceous plants and sphagnum moss. Structure in the surface tier is dominantly platy, but is granular or massive in some pedons. Layers within the control section have a hue of 2.5YR to 2.5Y; value of 2 to 5; and chroma of 0 to 4. Colors commonly become darker on brief exposure to air.

The subsurface and bottom tiers range from platy structure to massive. Reaction throughout the control section ranges from extremely acid to very strongly acid in water (pH less than 4.5 in 0.01M calcium chloride).

Podunk Series

The Podunk series consists of very deep, moderately well drained soils on flood plains in intermontane valleys of the Adirondack Upland. Podunk soils formed in loamy sediments deposited by floodwaters. Slopes range from 0 to 3 percent.

Podunk soils are associated on the landscape with Ondawa, Rumney, Burnt Vly, Adams, Monadnock, Becket, and Tunbridge soils. Ondawa soils are well drained. Rumney soils are poorly drained. Burnt Vly soils are mucky and very poorly drained. Adams soils are sandy and somewhat excessively drained. Monadnock soils are loamy over sandy or gravelly and are well drained. Becket soils are well drained and have a compact substratum. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock and are well drained.

Typical pedon of Podunk very fine sandy loam, 0 to 3 percent slopes, in an idle hay field, town of North Elba, 1 mile north on Riverside Drive (Co. Rte. 21) from NY State Route 73, then 50 feet southeast into field; USGS Lake Placid, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 15 minutes 59 seconds N. and long. 73 degrees 57 minutes 04 seconds W.

Ap—0 to 7 inches; very dark grayish brown (10YR 3/2) very fine sandy loam, light brownish gray (10YR 6/2) dry; weak medium and fine granular structure; very friable; many very fine and common fine roots; moderately acid; abrupt smooth boundary.

Bw1—7 to 11 inches; dark yellowish brown (10YR 4/4) very fine sandy loam; weak medium and fine subangular blocky structure; very friable; common fine and very fine roots; strongly acid; clear wavy boundary.

Bw2—11 to 18 inches; yellowish brown (10YR 5/4) fine sandy loam; weak medium and fine subangular blocky structure; very friable; few fine and common very fine roots; few medium distinct gray brown (10YR 5/2) iron depletions and few fine prominent yellowish brown (10YR 5/8) masses of iron accumulation; strongly acid; clear wavy boundary.

C—18 to 31 inches; brown (10YR 5/3) loamy fine sand; massive; very friable; few very fine roots in upper part; common medium and coarse faint grayish brown (10YR 5/2) and common medium faint light brownish gray (10YR 6/2) iron depletions, and common fine distinct yellowish brown (10YR 5/6) masses of iron accumulation; strongly acid; abrupt wavy boundary.

Ab—31 to 34 inches; dark brown (10YR 3/3) very fine sandy loam; massive; very friable; strongly acid; clear wavy boundary.

C'1—34 to 39 inches; brown (10YR 4/3) very fine sandy loam; massive; very friable; common medium and coarse distinct gray (10YR 5/1) and common medium faint grayish brown (10YR 5/2) iron depletions, and common fine prominent yellowish red (5YR 4/6) masses of iron accumulation; strongly acid; gradual wavy boundary.

C'2—39 to 45 inches; brown (10YR 4/3) fine sandy loam; massive; very friable; 2 percent rock fragments; common medium and coarse faint grayish brown (10YR 5/2) iron depletions, and few fine prominent yellowish red (5YR 4/6) masses of iron accumulation; moderately acid; clear wavy boundary.

C’3—45 to 53 inches; brown (10YR 5/3) sand; single grain; loose; 2 percent rock fragments; common medium faint grayish brown (10YR 5/2) and light brownish gray (10YR 6/2) iron depletions, and common medium and fine prominent strong brown (7.5YR 5/8) masses of iron accumulation; moderately acid; abrupt wavy boundary.

C’4—53 to 72 inches; grayish brown (10YR 5/2) sand; single grain; loose; few medium and fine faint light brownish gray (10YR 6/2) iron depletions, and common fine prominent strong brown (7.5YR 5/6) masses of iron accumulation; moderately acid; abrupt wavy boundary.

The thickness of the solum and depth to the coarse-textured substratum ranges from 18 to 40 inches. Depth to bedrock is more than 60 inches. Rock fragments in the solum are less than 15 percent of the volume and range from 0 to 40 percent in the substratum.

Reaction ranges from very strongly acid to slightly acid throughout. Some pedons have buried horizons.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 2 to 4. Dry value is 6 or 7. Texture is very fine sandy loam, fine sandy loam, sandy loam, or loam. The horizon has weak or moderate, very fine or fine granular structure.

The Bw horizon has hue of 10YR to 5Y, with value and chroma of 2 to 6. Texture is very fine sandy loam, fine sandy loam, sandy loam, or loam. The horizon has weak or moderate very fine or fine granular or subangular blocky structure. Consistence is very friable or friable.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 6. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are thin loamy and/or extremely gravelly strata. Also, some pedons have a loamy C horizon layer just] below the Bw horizon. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and friable or very friable.

Correlation Note: The PoA map unit have very fine sandy loam textures in the upper solum that are not typical for the range of the Podunk series. This should not significantly affect use and management on a local basis for most purposes.

Pootatuck Series

The Pootatuck series consists of very deep, moderately well drained soils on flood plains in the Champlain Valley. Pootatuck soils formed in loamy sediments deposited by floodwaters. Slopes range from 0 to 3 percent.

Pootatuck soils are associated on the landscape with Occum, Rippowam, Vergennes, Windsor, Chatfield, and Hollis soils. Occum soils are well drained. Rippowam soils are poorly drained. Vergennes soils are clayey. Windsor soils are sandy and are excessively drained. Chatfield and Hollis soils are well drained and are 20 to 40 inches and 10 to 20 inches deep to meta-igneous bedrock respectively.

Typical pedon of Pootatuck fine sandy loam, 0 to 3 percent slopes, in the town of Chesterfield, 1.4 miles west on Burke Road from the Clintonville Bridge, then 400 feet north of road, in a hay field; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 27 minutes 28 seconds N. and long. 73 degrees 36 minutes 03 seconds W.

Ap—0 to 5 inches, dark brown (10YR 3/3) fine sandy loam; pale brown (10YR 6/3) dry; moderate fine and medium granular structure; very friable; many fine roots and few medium roots; moderately acid; abrupt smooth boundary.

Bw1—5 to 9 inches, dark yellowish brown (10YR 4/4) sandy loam; weak fine subangular blocky structure; very friable; many fine roots; slightly acid; abrupt wavy boundary.

Bw2—9 to 14 inches, brown (10YR 4/3) fine sandy loam; weak medium subangular blocky structure; very friable; common fine roots; common fine faint brown (7.5YR 4/4) soft masses of iron accumulation; slightly acid; gradual wavy boundary.
Bw3—14 to 21 inches, brown (10YR 4/3 and 5/3) fine sandy loam; weak medium and coarse subangular blocky structure; very friable; few fine roots; common fine distinct dark yellowish brown (10YR 4/6) and brown (7.5YR 4/4) soft masses of iron accumulation, few fine faint grayish brown (10YR 5/2) and light brownish gray (10YR 6/2) iron depletions in the lower part; slightly acid; abrupt wavy boundary.
C1—21 to 32 inches, brown (10YR 5/3) and pale brown (10YR 6/3) loamy fine sand; massive; very friable; few fine roots in upper part; common medium and coarse dark yellowish brown (10YR 4/4 and 4/6) soft masses of iron accumulation, few fine faint light brownish gray (10YR 6/2) iron depletions; slightly acid; clear wavy boundary.
C2—32 to 47 inches, grayish brown (2.5Y 5/2) loamy fine sand; massive; very friable; few medium prominent strong brown (7.5YR 5/6) and common fine and medium distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation, few fine faint gray (10YR 5/1) iron depletions; slightly acid; gradual wavy boundary.
C3—47 to 72 inches, dark grayish brown (10YR 4/2) loamy sand; single grain; loose; common fine and medium faint brown (10YR 4/3) and few medium prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; slightly acid.

The thickness of the solum and depth to the coarse-textured substratum range from 20 to 40 inches. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 40 percent in the substratum. Some pedons have up to 15 percent cobbles in the substratum. Unless limed, reaction ranges very strongly acid to slightly acid.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. Texture is loam, very fine sandy loam, fine sandy loam, or sandy loam. This horizon has weak or moderate granular structure and is friable or very friable.

The Bw horizon has hue of 10YR to 5Y and value and chroma of 3 to 6. Iron depletions are above a depth of 24 inches. The Bw horizon is dominantly fine sandy loam or sandy loam, but includes thin strata of loam, very fine sandy loam, or silt loam. The horizon has granular or subangular blocky structure, or is massive. Consistence is friable or very friable.

Some pedons have thin Ab horizon strata.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 6. It is typically has redoximorphic features in some subhorizon. Texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are thin loamy and/or extremely gravelly strata. Also, some pedons have a loamy C horizon layer just below the Bw horizon. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and friable or very friable. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of the alluvial deposits.

Pyrities Series

The Pyrities series consists of very deep, well drained soils on summits, shoulders, backslopes, and footslopes of glaciated hills and ridges, and on till plains in the eastern foothills of the Adirondack High Peaks Region. Pyrities soils formed in loamy sediments underlain by firm, calcareous lodgment till. Slopes range from 3 to 35 percent.

Pyrities soils are associated on the landscape with Nehasne, Kalurah, Malone, Typic Endoaquolls, Monadnock, and Tunbridge soils. Nehasne soils are moderately deep to marble bedrock. Kalurah soils are moderately well drained. Malone soils are somewhat poorly drained. Typic Endoaquolls soils are poorly drained. Monadnock soils are more acid, and are sandy or gravelly in the substratum. Tunbridge soils are 20 to 40 inches

deep to meta-igneous bedrock, and are more acid.

Typical pedon of Pyrities fine sandy loam, 3 to 8 percent slopes, in a wooded area, town of Essex, 350 feet north of a point on Jersey Street, that is 2,970 feet east of the junction of Jersey Street and Brookfield Road; USGS Willsboro, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 18 minutes 10 seconds N. and long. 73 degrees 26 minutes 10 seconds W.

A—0 to 4 inches; very dark grayish brown (10YR 3/2) fine sandy loam, light brownish gray (10YR 6/2) dry; moderate fine and medium granular structure; friable; many fine and very fine and common medium roots; 5 percent rock fragments; moderately acid; abrupt smooth boundary.

E/B—4 to 7 inches; brown (10YR 5/3) (E part) and yellowish brown (10YR 5/6) (B part) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and very fine and few medium roots; 7 percent rock fragments; moderately acid; clear smooth boundary.

Bw1—7 to 11 inches; yellowish brown (10YR 5/6) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and medium roots; 7 percent rock fragments; slightly acid; clear wavy boundary.

Bw2—11 to 20 inches; dark yellowish brown (10YR 4/6) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and medium roots; 7 percent rock fragments; slightly acid; clear wavy boundary.

BC—20 to 28 inches; light olive brown (2.5Y 5/4) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and few medium roots; 7 percent rock fragments; slightly acid; clear wavy boundary.

C1—28 to 54 inches; olive brown (2.5Y 4/4) sandy loam; massive with medium and thick plate-like divisions; friable; 10 percent rock fragments; neutral; gradual smooth boundary.

C2—54 to 72 inches; grayish brown (2.5Y 5/2) sandy loam; massive with medium and thick plate-like divisions; firm; 10 percent rock fragments; slightly effervescent, moderately alkaline.

The thickness of the solum ranges from 25 to 50 inches. Bedrock is deeper than 60 inches. The depth of free carbonates ranges from 40 to 80 inches. Rock fragments range from 5 to 35 percent by volume in the A and B horizons and from 5 to 50 percent in the C horizon.

The A or Ap horizon has hue of 7.5YR or 10YR, value of 2 to 4, and chroma of 1 to 3. Texture is commonly fine sandy loam and less commonly is silt loam or loam. Structure is weak or moderate, granular or subangular blocky. Consistence is friable or very friable. Reaction ranges from moderately acid to neutral.

Some pedons have an E horizon with hue of 7.5YR or 10YR, value of 5 or 6, and chroma 1 through 3. Texture is fine sandy loam, sandy loam, or loam. Structure is weak or moderate, granular or subangular blocky. Consistence is friable or very friable. Reaction ranges from moderately acid through neutral.

The Bw horizon has hue of 7.5YR or 10YR, value 3 to 5, and chroma of 3 to 6. Texture is commonly fine sandy loam and less commonly sandy loam or loam. Structure is weak or moderate subangular blocky. Consistence is friable or very friable. Reaction ranges from slightly acid to slightly alkaline.

The BC horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is fine sandy loam, sandy loam, or loam. Structure is weak or moderate, platy or subangular blocky. Consistence is friable. Reaction ranges from slightly acid through slightly alkaline.

The C horizon has hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 2 to 4. Texture is fine sandy loam, sandy loam or loam. Some pedons have thin layers of loamy sand. Structure is massive, or massive with plate-like divisions. Consistence is friable or firm. Reaction ranges from slightly acid to moderately alkaline.

Rawsonville Series

The Rawsonville series consists of moderately deep, well drained soils on summits, shoulders, and backslopes of glaciated mountains, hills, and ridges in the Adirondack Upland. Rawsonville soils formed in loamy sediments deposited by glacial ice and are underlain by meta-igneous bedrock. Slopes range from 3 to 60 percent.

Rawsonville soils are associated on the landscape with Hogback, Knob Lock, Mundalite, Worden, and Wilmington soils. Hogback soils are 10 to 20 inches deep to meta-igneous bedrock. Knob Lock soils are mucky and are 1 to 20 inches deep to meta-igneous bedrock. Mundalite soils are very deep. Worden soils are very deep and somewhat poorly drained. Wilmington soils are very deep and poorly drained.

Typical pedon of Rawsonville loam, in a map unit of Rawsonville-Hogback complex, 35 to 60 percent slopes, very rocky, very bouldery, in a forested area, in the town of Newcomb, approximately 100 feet east of the summit of Catlin Mountain; USGS Santanoni 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 01 minutes 00 seconds N. and long. 74 degrees 13 minutes 56 seconds W.

English units approximate original depths taken in metric for this pedon.

Oi—0 to 1 inch, brown (10YR 4/3) slightly decomposed hardwood and conifer organic debris; about 95 percent fiber, 90 percent rubbed; extremely acid; clear smooth boundary.

Oe—1 to 2 inches, dark reddish brown (5YR 3/2) moderately decomposed plant material; about 70 percent fiber, 60 percent rubbed; many fine and few medium roots; 5 percent cobbles; extremely acid; clear smooth boundary.

A—2 to 3 inches, dark reddish brown (5YR 3/2) loam; weak fine granular structure; very friable; common fine skeletans; many fine roots; 5 percent cobbles; extremely acid; clear broken boundary.

E—3 to 4 inches, dark reddish gray (5YR 4/2) fine sandy loam; weak fine granular structure; very friable; many fine roots; 2 percent gravels and 5 percent cobbles; extremely acid; clear wavy boundary.

Bhs1—4 to 5 inches, dark reddish brown (5YR 2.5/2) fine sandy loam; weak fine subangular blocky parting to weak fine granular structure; friable; few fine skeletans; few fine pores; many fine roots; 2 percent gravels and 5 percent cobbles; extremely acid; clear wavy boundary.

Bhs2—5 to 11 inches, dark reddish brown (5YR 3/2) fine sandy loam; weak fine granular structure; very friable; very few fine skeletans; many fine roots; 3 percent gravels and 5 percent cobbles; very strongly acid; clear wavy boundary.

Bs—11 to 20 inches, dark reddish brown (5YR 3/4); fine sandy loam; weak fine subangular blocky structure; firm; few fine pores; few fine roots; 5 percent gravels and 2 percent cobbles; very strongly acid; clear wavy boundary.

BC—20 to 25 inches, dark yellowish brown (10YR 4/4) fine sandy loam; moderate thin platy structure; brittle; firm; very few fine pores; very few fine roots; 5 percent gravels; common medium distinct strong brown (7.5YR 5/6) and few fine prominent dark red (2.5YR 3/6) mottles; very strongly acid; abrupt wavy boundary.

R—25 inches, meta-anorthosite bedrock.

The thickness of the solum and depth to bedrock range from 20 to 40 inches. Reaction ranges from extremely acid to strongly acid throughout the mineral soil. Rock fragments are mostly gravel, cobbles or channers and range from 0 to 20 percent in the upper part of the solum and 5 to 30 percent in the lower part of the solum.

Some pedons have an A horizon that is neutral or has hue of 5YR to 10YR, value of 2 to 3, and chroma of 0 to 2. Texture is fine sandy loam, very fine sandy loam, silt loam, or loam in the fine-earth fraction.

The E horizon has hue of 5YR to 5Y, value of 3 to 6, and chroma of 1 to 3. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam in the fine-earth fraction.

The Bhs horizon has hue of 2.5YR to 7.5YR with value and chroma of 3 or less.

Some pedons have a Bh horizon that is neutral with value of 2 or less or has hue of 10YR, value of 3 and chroma of 1.

Some pedons have a Bs horizon with hue of 5YR to 10YR, value of 3 or more and chroma of 4 or more. The Bhs, Bs, and Bh horizons are sandy loam, fine sandy loam, very fine sandy loam, silt loam, or loam in the fine-earth fraction. They are moderately or weakly smeary.

The BC horizon has hue of 7.5YR to 5Y value of 3 to 5, and chroma of 2 to 4. Texture is sandy loam, fine sandy loam or very fine sandy loam in the fine-earth fraction.

Some pedons have a C horizon with hue of 10YR to 5Y, value of 3 to 5, and chroma of 2 to 4. Texture is sandy loam, fine sandy loam or very fine sandy loam in the fine-earth fraction.

Bedrock is slightly weathered schist, gneiss, phyllite, granite, or anorthosite.

Ricker Series

The Ricker series consists of very shallow and shallow, well drained to excessively drained soils on summits, shoulders, and backslopes of glaciated mountains, hills, and ridges in the Adirondack High Peaks Area. Ricker soils formed in decomposing plant material, sometimes underlain by a thin (less than 4 inch) mineral soil layer, directly over meta-igneous bedrock. Slopes range from 15 to 80 percent.

Ricker soils are associated on the landscape with Esther, Andic Cryaquods, Wallface, Santanoni, Skylight, and Couchsachraga soils. Esther soils are loamy, very deep, and moderately well drained. Andic Cryaquods soils are loamy, very deep, and somewhat poorly drained. Wallface soils are loamy and are moderately deep to meta-igneous bedrock. Santanoni soils are sandy and gravelly, moderately deep to meta-igneous bedrock, and are somewhat excessively to excessively drained. Skylight and Couchsachraga soils are sandy, and are shallow and very shallow to meta-igneous bedrock respectively.

Typical pedon of Ricker soils, in a map unit of Ricker-Couchsachraga-Skylight complex, 35 to 80 percent slopes, very rocky, very bouldery, in a forested area, in the town of Keene, summit of Allen Mountain, 50 feet north of summit marker; USGS Mount Marcy 15 minute topographic quadrangle; NAD 1927; and lat. 44 degrees 04 minutes 16 seconds N. and long. 73 degrees 56 minutes 24 seconds W.

Oi—0 to 1 inch; slightly decomposed needles and woody fragments.

Oe—1 to 6 inches, black (5YR 2.5/1) broken face and pressed, and dark reddish brown (5YR 2.5/2) rubbed moderately decomposed plant (hemic} material; 75 percent fiber unrubbed, and 30 percent fiber rubbed; moderate fine granular structure; very friable; many fine and common medium roots; extremely acid; clear smooth boundary.

Oa—6 to 11 inches, black (7.5YR 2.5/1) broken face, rubbed, and pressed highly decomposed plant (sapric) material; 20 percent fiber unrubbed, and 5 percent fiber rubbed; moderate fine and medium granular structure; very friable; common fine and few medium roots; up to 10 percent mineral in lower part; extremely acid; abrupt wavy boundary.

R—11 inches, Marcy anorthosite bedrock.

The depth to bedrock ranges from 1 to 20 inches. Very thin mineral layers are at the bedrock interface in most pedons. Rock fragments range from 0 to 50 percent in the mineral layers. The organic material is ultra acid or extremely acid and the mineral layers are extremely or very strongly acid.

The Oi horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 4, and chroma of 0 to 4. It is slightly decomposed leaves, needles, twigs, and moss (fibric material).

The Oe horizon is neutral or has hue of 2.5YR to 10YR, value of 2 or 3, and chroma of 0 to 6. It is moderately decomposed organic matter (hemic material).

The Oa horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 5, and chroma of 0 to 2. It is highly decomposed organic matter (sapric material).

The mineral horizons have hue of 5YR to 5B, value of 2 to 7, and chroma of 1 to 3. They are E, Bh, Bhs, or C horizons. Texture is coarse sand, sand, loamy sand, loamy fine sand, sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam in the fine-earth.

Rippowam Series

The Rippowam series consists of very deep, poorly drained soils on flood plains in the Champlain Valley. Rippowam soils formed in loamy sediments deposited by flood waters. Slopes range from 0 to 3 percent.

Rippowam soils are associated on the landscape with Occum, Pootatuck, Windsor, Deerfield, Vergennes, Kingsbury, and Claverack soils. Occum soils are well drained. Pootatuck soils are moderately well drained. Windsor and Deerfield soils are sandy and are excessively drained and moderately well drained respectively. Vergennes and Kingsbury soils are clayey and moderately well drained and somewhat poorly drained respectively. Claverack soils are sandy over clayey and are moderately well drained.

Typical pedon of Rippowam fine sandy loam, 0 to 3 percent slopes, in the town of Chesterfield, 1.5 miles west on Burke Road from the Clintonville Bridge, to an old house and barn at the end of the road, then 250 feet north of house, in a hay field; USGS Ausable Forks, NY topographic quadrangle; NAD 1927; lat. 44 degrees 27 minutes 25 seconds N. and long. 73 degrees 36 minutes 11 seconds W.

Oe—0 to 2 inches, dark reddish brown (5YR 3/3) and dark brown (7.5YR 3/2) mucky peat; weak fine granular structure; very friable; many fine roots and few medium roots, moderately acid; abrupt smooth boundary.

Ap—2 to 11 inches, very dark gray (10YR 3/1) fine sandy loam; gray (10YR 6/1 dry); weak medium subangular blocky parting to weak fine granular structure; very friable; common fine roots, few medium and coarse roots; less than 1 percent rock fragments; common fine and medium prominent strong brown (7.5YR 4/6) and brown (7.5YR 4/4) soft masses of iron accumulation along root channels; moderately acid; abrupt smooth boundary.

Cg1—11 to 21 inches, light brownish gray (2.5Y 6/2) and gray (10YR 5/1) fine sandy loam, with lenses of loamy fine sand and loamy sand; massive; very friable; common fine and few medium roots; few fine and medium pores; less than 1 percent rock fragments; moderate medium and coarse prominent strong brown (7.5YR 4/6) and many fine prominent dark brown (7.5YR 3/4) soft masses of iron accumulation (total 50 percent of the horizon); slightly acid; clear smooth boundary.

Cg2—21 to 29 inches, gray (10YR 5/1) fine sandy loam, with common lenses of very fine sandy loam; massive; very friable; few fine roots; few fine and medium pores; less than 1 percent rock fragments; common medium and coarse prominent dark reddish brown (5YR 3/3) and light brown (7.5YR 6/4) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Cg3—29 to 36 inches, grayish brown (2.5Y 5/2) fine sandy loam; massive; very friable; few fine roots; few fine and medium pores; less than 1 percent rock fragments; common medium and coarse prominent dark yellowish brown (10YR 4/4 and 4/6) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Cg4—36 to 43 inches, grayish brown (10YR 5/2) fine sandy loam; massive, with some inherited depositional plates; very friable; few fine roots; less than 1 percent rock fragments; few fine distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation along root channels; slightly acid; clear wavy boundary.

Cg5—43 to 72 inches, dark grayish brown (10YR 4/2) very gravelly loamy sand; single

grain; loose; 40 percent rock fragments; common medium and coarse distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation; slightly acid.

The thickness of the solum ranges from 20 to 40 inches. The difference between mean summer soil temperature and mean winter soil temperature is at least 25 degrees F. or more. Depth to the coarse-textured substratum layers commonly is from 20 to 40 inches but can range to a depth of 45 inches. Gravel ranges from 0 to 15 percent by volume in the solum and from 0 to 40 percent in the sandy substratum. Some pedons have up to 10 percent cobbles in the coarse-textured substratum. Reaction ranges from very strongly acid to neutral with some subhorizon being moderately acid, slightly acid, or neutral within a depth of 40 inches.

Some pedons have an O horizon that is highly decomposed, moderately decomposed, or slightly decomposed plant material. The horizon has hue of 5YR to 10YR and value and chroma of 3 or less.

The A or Ap horizon has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 or 2. Texture is very fine sandy loam, fine sandy loam, or sandy loam. It typically has weak or moderate granular structure but some pedons have subangular blocky structure. Consistence is friable or very friable.

The Bg horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 or 2 and typically has redoximorphic features. Texture of the Bg horizon is dominantly fine sandy loam or sandy loam. The Bg horizon is massive or has weak granular or subangular blocky structure. Consistence is friable or very friable.

The BCg horizon, where present, has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 or 4 and typically has redoximorphic features. Texture of the BCg horizon is dominantly fine sandy loam or sandy loam. The BCg horizon is massive or has weak granular or subangular blocky structure. Consistence is friable or very friable.

Included in some pedons are thin Ab horizons with characteristics similar to the A horizon.

The C horizon or layer has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Texture ranges from loamy fine sand to coarse sand in the fine-earth fraction. The C horizon is typically single grain and loose. Some pedons have thin loamy strata and/or extremely gravelly strata in the lower part of the C horizon.

Correlation Note: The RmA map unit is a taxadjunct to the Rippowam series because the pedon qualifies as not having a Cambic horizon. The classification of the taxadjunct is Coarse-loamy, mixed, superactive, nonacid, mesic Aeric Fluvaquents. This is the former classification of the Rippowam series prior to changes regarding the Cambic horizon in Soil Taxonomy in 1999. The present Rippowam classification is Coarse-loamy, mixed, superactive, nonacid, mesic Fluvaquentic Endoaquepts. This should not significantly affect use and management on a local basis for most purposes.

Roundabout Series

The Roundabout series consists of very deep, somewhat poorly drained soils on lacustrine terraces in intermontane valleys of the Adirondack Uplands. Roundabout soils formed in silt and very fine sand sediments deposited by wind or in still water. Slopes range from 0 to 3 percent.

Roundabout soils are associated on the landscape with Nicholville, Hailesboro, Wegatchie, Becket, Skerry, Kalurah, and Champlain soils. Nicholville soils are moderately well drained. Hailesboro and Wegatchie soils have higher clay content. Becket soils are loamy and well drained. Skerry and Kalurah soils are loamy and moderately well drained. Champlain soils are sandy and somewhat excessively drained.

Typical pedon of Roundabout silt loam, 0 to 3 percent slopes, in a hay field, in the town of Jay, 70 feet southeast of a point on North Jay Road, that is 3,500 feet southwest of the junction of North Jay Road and Hazen Road; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 22 minutes 30 seconds N. and long. 73 degrees 41 minutes 02 seconds W.

Ap—0-11 inches, very dark grayish brown (10YR 3/2) silt loam; light brownish gray (10YR 6/2) dry; weak medium subangular blocky structure; friable; common fine and very fine roots; many medium prominent strong brown (7.5YR 4/6) stains along root channels; slightly acid; clear smooth boundary.

Bw—11-19 inches, light olive brown (2.5Y 5/3) very fine sandy loam; weak medium subangular blocky structure; friable; few very fine and fine roots; common medium distinct yellowish brown (10YR 5/6) masses of iron accumulation, common medium distinct grayish brown (2.5Y 5/2) areas of iron depletion; slightly acid; clear smooth boundary.

Bg—19-28 inches; grayish brown (10YR 5/2) very fine sandy loam; weak medium subangular blocky structure; friable; few very fine roots; many medium and coarse prominent reddish brown (5YR 4/4) masses of iron accumulation; slightly acid; gradual smooth boundary.

Cg1—28-42 inches, gray (10YR 6/1) very fine sandy loam; massive, varved; friable; moderate medium and coarse distinct (10YR 4/4) masses of iron accumulation; slightly acid; clear smooth boundary.

Cg2—42-72 inches, dark grayish brown (10YR 4/2) and gray (10YR 6/1) silt loam; massive, varved; firm; common medium prominent black (7.5YR 2.5/1) manganese stains; slightly acid.

The thickness of the mineral solum ranges from 16 to 48 inches. Depth to bedrock is more than 60 inches. Rock fragments, mostly gravel, are less than 5 percent by volume above 40 inches and from 0 to 20 percent below 40 inches. Reaction ranges from very strongly acid to slightly acid in the mineral solum and from moderately acid to neutral in the substratum. Some pedons below 40 inches range to moderately alkaline. Some subhorizon below the Ap horizon, within 20 inches of the mineral soil surface, has chroma of 2 or less with redox concentrations.

The Oa horizon, where present, has hue of 5YR to 10YR, value of 2 to 3, and chroma of 1 or 2. Structure is weak or moderate, very fine to medium granular.

The Ap horizon has hue of 10YR, value of 3 or 4, and chroma of 2 to 4. It has weak to strong, fine or medium, granular or subangular blocky structure. Undisturbed areas have an A horizon 1 to 6 inches thick that has hue of 7.5YR or 10YR, value of 3 to 5, and chroma of 1 or 2. Dry value for the Ap or A horizon is 6 or 7. It has weak or moderate very fine to medium granular or subangular blocky structure. Texture is silt loam or very fine sandy loam. Consistence is very friable or friable.

Some pedons have an E horizon with hue of 5Y, value of 5 to 7, and chroma of 1 or 2. It has weak or moderate, thin or medium platy, or weak fine granular structure. Texture is silt loam or very fine sandy loam. Consistence is very friable or friable.

The B horizon has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. It has faint to prominent redox concentrations. It is silt loam or very fine sandy loam. Structure is weak or moderate, thin to thick platy, weak or moderate very fine to medium subangular blocky, or weak fine granular. Some pedons have primary structure that is weak coarse or very coarse prismatic. Consistence is friable or firm.

The BC horizon has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. The horizon has faint to prominent redoximorphic features. Texture is silt loam or very fine sandy loam. Structure is weak or moderate, thin to thick platy. Consistence is friable or firm.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 1 to 4. It has faint to prominent redoximorphic features. Texture is silt loam or very fine sandy loam

and may have strata that range from silty clay loam to fine sand in some pedons. Below 40 inches some pedons have fine sand and gravelly sand. Structure is weak or moderate, thin to thick platy, weak medium to very coarse prismatic, or the horizon is structureless. Consistence is loose to very firm.

Rumney Series

The Rumney series consists of very deep, poorly drained soils on flood plains in intermontane valleys of the Adirondack Uplands. Rumney soils formed in loamy sediments deposited by flood waters. Slopes range from 0 to 3 percent.

Rumney soils are associated on the landscape with Podunk, Burnt Vly, Colton, Monadnock, Becket, and Tunbridge soils. Podunk soils are moderately well drained. Burnt Vly soils are mucky and very poorly drained. Colton soils are gravelly and excessively drained. Monadnock soils are loamy over sandy or gravelly, and are well drained. Becket soils are loamy and well drained. Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep over meta-igneous bedrock.

Typical pedon of Rumney loam, 0 to 3 percent slopes, in an idle pasture, town of Wilmington, 1,000 feet east of point on Haselton Road, that is 4,600 feet south along Haselton Road from the Clinton County line; USGS Ausable Forks 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 25 minutes 57 seconds N. and long. 73 degrees 44 minutes 52 seconds W.

Ap—0 to 7 inches; very dark grayish brown (10YR 3/2) loam, light brownish gray (10YR 6/2) dry; weak medium subangular blocky parting to weak medium granular structure; friable; many very fine and few fine roots; many fine prominent reddish brown (5YR 4/4) masses of iron accumulation in pore linings; slightly acid; abrupt smooth boundary.

Bw—7 to 12 inches; brown (10YR 4/3) fine sandy loam; weak medium subangular blocky structure; friable; common very fine roots; less than 1 percent pebbles; common fine and medium distinct yellowish brown (10YR 5/6) and common medium faint brown (10YR 5/3) masses of iron accumulation, and common fine faint dark grayish brown (10YR 4/2) iron depletions along pores; moderately acid; clear smooth boundary.

Bg1—12 to 19 inches; dark grayish brown (10YR 4/2) loam; weak coarse and medium subangular blocky structure; very friable; common very fine roots; less than 1 percent pebbles; common medium prominent yellowish brown (10YR 5/6) and common medium faint dark yellowish brown (10YR 4/4) masses of iron accumulation, common fine distinct yellowish brown (10YR 5/4) masses of iron accumulation on pore linings, common fine distinct brown (7.5YR 4/4) soft iron nodules, and few coarse faint dark gray (10YR 4/1) iron depletions; moderately acid; gradual smooth boundary.

Bg2—19 to 30 inches; dark grayish brown (10YR 4/2) fine sandy loam; weak coarse and medium subangular blocky structure; friable; few very fine roots in upper part; less than 1 percent cobbles; common medium and coarse prominent yellowish red (5YR 4/6) masses of iron accumulation and common fine and medium prominent reddish brown (5YR 4/4) iron nodules; slightly acid; clear smooth boundary.

C1—30 to 33 inches; brown (7.5YR 4/4) fine sandy loam; massive; friable; less than 1 percent gravel; common fine and medium faint reddish brown (5YR 4/4) iron nodules and many coarse and medium prominent grayish brown (2.5Y 5/2) iron depletions; slightly acid; abrupt smooth boundary.

C2—33 to 48 inches; grayish brown (10YR 5/2) very gravelly loamy sand; single grain; loose; 35 percent gravels and 5 percent cobbles; after 30 seconds yellowish brown (10YR 5/4) and dark yellowish brown (10YR 4/4) matrix colors; moderately acid; abrupt smooth boundary.

C3—48 to 54 inches; dark gray (5Y 4/1) silt loam; massive; friable, slightly sticky, nonplastic; slightly acid; clear smooth boundary.
C4—54 to 72 inches; gray (10YR 5/1) very gravelly loamy sand; single grain; loose; 40 percent gravels; moderately acid.

The thickness of the solum and depth to the coarse textured substratum ranges from 20 to 40 inches. Depth to bedrock is more than 60 inches. Gravel content ranges from 0 to 15 percent by volume in the solum and from 0 to 40 percent in the substratum. Reaction ranges from very strongly acid to neutral throughout, but some subhorizon within 40 inches of the mineral soil surface is moderately acid to neutral. Some pedons are slightly alkaline below 40 inches. Some pedons have buried horizons.

The Ap, or A horizon where present, has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 to 3. Dry value is 6 or more. Texture is sandy loam, fine sandy loam, very fine sandy loam, loam, or silt loam. It has weak or moderate, fine or medium granular structure and is very friable or friable. A horizons can have blocky structure.

The B horizon has hue of 10YR to 5Y, value of 3 to 6, and chroma of 1 to 4. At least one subhorizon within 20 inches of the mineral soil surface has hue of 10YR or 2.5Y, with value of 3 to 5, and chroma of 2. It has common or many, fine to coarse, faint to prominent redoximorphic features. Texture is sandy loam, fine sandy loam, or loam. Some pedons have thin subhorizons of very fine sandy loam in the upper part of the B horizon. The horizon has weak or moderate, very fine to coarse subangular blocky or very fine to medium granular structure, and is very friable or friable.

Some pedons may have a Bw horizon.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 1 to 4. The texture of individual layers ranges from loamy fine sand to coarse sand in the fine-earth fraction. Included in some pedons are loamy and/or extremely gravelly strata. The thickness and number of subhorizons is variable and corresponds to the thickness and variability of the alluvial deposits. The C horizon is single grain and loose in the sandy part. The loamy part is typically massive and very friable or friable.

Santanoni Series

Santanoni soils consist of moderately deep, somewhat excessively drained and excessively drained soils on backslopes of glaciated mountains in the Adirondack High Peaks Area. These soils formed in sandy and gravelly colluvial materials originally deposited by glacial ice, and are underlain by meta-igneous bedrock. Slopes range from 35 to 80 percent.

Santanoni soils are associated on the landscape with Andic Cryaquods, Couchsachraga, Ricker, Esther, Skylight, and Wallface soils. Andic Cryaquods soils are loamy, very deep, and somewhat poorly drained. Couchsachraga soils are sandy and very shallow to bedrock. Ricker soils are organic, shallow or very shallow to bedrock, and are well drained to excessively drained. Esther soils are loamy, very deep, and moderately well drained. Skylight soils are sandy and are moderately deep to bedrock. Wallface soils are loamy, moderately deep to bedrock, and are well drained.

Typical pedon of Santanoni gravelly loamy sand, in a map unit of Santanoni-Skylight complex, 35 to 80 percent slopes, very rocky, very bouldery, in a wooded area, in the town of Wilmington, 2,050 feet east of apex of the lower hairpin curve on Whiteface Memorial Highway toward the upper hairpin curve, and 160 feet south up a landslide scar, on west side of slide scar; USGS Lake Placid, NY topographic quadrangle; NAD 1983; lat. 44 degrees 22 minutes 07.5 seconds N. and long. 73 degrees 54 minutes 19.3 seconds W.

Oe—0 to 2 inches; dark reddish brown (5YR 2.5/2) moderately decomposed (hemic) plant material comprised of sphagnum moss, conifer needles, and roots; weak fine

and medium granular structure; very friable; many very fine and fine, and common medium roots; extremely acid; abrupt wavy boundary.

E—2 to 3 inches; gray (5YR 5/1) gravelly loamy sand; weak fine and medium granular structure; very friable; many fine and very fine, and few medium roots; 20 percent gravel; extremely acid; abrupt wavy boundary.

Bhs1—3 to 7 inches; dark reddish brown (5YR 2.5/2) stony loamy coarse sand; moderate fine and medium granular structure; very friable; strongly smeary; many very fine and fine and common medium roots; 13 percent gravel, 10 percent cobbles, and 5 percent stones; extremely acid; clear wavy boundary.

Bhs2—7 to 14 inches; dark reddish brown (5YR 3/3) very gravelly loamy coarse sand; moderate fine and medium subangular blocky structure; very friable; moderately smeary; common very fine and fine and few medium roots; 30 percent gravel, 10 percent cobbles, and 5 percent stones; extremely acid; gradual wavy boundary.

Bs—14 to 31 inches; reddish brown (5YR 4/4) very gravelly loamy coarse sand; weak medium subangular blocky structure; friable; few very fine and fine roots; 39 percent gravel, 5 percent cobbles, and 15 percent stones; very strongly acid; gradual wavy boundary.

BC—31 to 39 inches; brown; (10YR 4/3) very stony coarse sand; weak medium and coarse subangular blocky structure; friable; 20 percent gravel, 10 percent cobbles, and 5 percent stones; very strongly acid; abrupt wavy boundary.

R—39 inches; Whiteface anorthosite bedrock.

The thickness of the solum and depth to bedrock ranges from 20 to 40 inches from the mineral surface. Rock fragments range from 15 to 50 percent in the upper part of the mineral solum and from 35 to 70 percent in the lower part of the mineral solum, with 35 or greater percent weighted average by volume between a depth of 10 inches and the bedrock contact. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. It is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) material. The horizon has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The E horizon has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is loamy fine sand, loamy sand, or loamy coarse sand in the fine-earth fraction. It has weak fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The Bhs horizons, and Bh horizons (where present), have hue of 10R to 7.5YR, with value and chroma of 3 or less. The Bhs and Bh horizons are loamy fine sand, loamy sand, or loamy coarse sand in the fine earth fraction. Thin horizons of sandy loam or coarse sandy loam are present in some pedons. Ortstein is present in less than 50 percent of some horizons. They have weak or moderate, fine, medium, or coarse granular or subangular blocky structure. Some pedons have weak platy structure. Consistence is very friable to firm. Consistence is moderately or strongly smeary.

The Bs horizon has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is loamy fine sand, loamy sand, loamy coarse sand, sand, or coarse sand in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, or are single grain. Consistence is very friable, friable, or loose.

The BC horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is loamy fine sand, loamy sand, loamy coarse sand, sand, or coarse sand in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, or are single grain. Consistence is very friable, friable, or loose.

Bedrock is anorthositic gneiss (metamorphosed anorthosite).

Searsport Series

The Searsport series consists of very deep, very poorly drained sandy soils in depressions on deltas, outwash plains and outwash terraces in the Adirondack Upland. Searsport soils formed in stratified, water deposited sediments. Slope ranges from 0 to 3 percent.

Searsport soils are associated on the landscape with Naumburg, Croghan, Rumney, Burnt Vly, and Monadnock soils. Naumburg soils are somewhat poorly drained. Croghan soils are moderately well drained. Rumney soils are loamy and poorly drained. Burnt Vly soils have deeper muck deposits. Monadnock soils are loamy over sandy or gravelly, and are well drained.

Typical pedon of Searsport peat, in a map unit of Searsport-Haplosaprists-Naumburg complex, 0 to 3 percent slopes, in a wooded area, town of North Elba, 1,000 feet south on old Penn Central rail line from Route 86, then 200 feet west into woods; USGS Saranac Lake 15 minute topographic quadrangle; NAD 44 degrees 18 minutes 07 seconds north latitude, 74 degrees 06 minutes 41 seconds west longitude; NAD 1927.

Oi—0 to 4 inches; very dark brown (10YR 2/2) peat; weak medium granular structure; very friable; few fine, medium, and coarse roots; strongly acid; clear smooth boundary.

Oa—4 to 9 inches; black (10YR 2/1) muck; weak medium granular structure; very friable; few fine, medium, and coarse roots; strongly acid; clear smooth boundary.

A—9 to 14 inches; black (10YR 2/1) mucky sand, gray (10YR 5/1) dry; weak medium granular structure; very friable; strongly acid; clear wavy boundary.

Cg1—14 to 22 inches; dark gray (10YR 4/1) sand; single grain; loose; moderately acid; gradual wavy boundary.

Cg2—22 to 32 inches; gray (10YR 5/1) sand; single grain; loose; very strongly acid; clear wavy boundary.

Cg3—32 to 40 inches; gray (5Y 5/1) loamy fine sand; massive; very friable; slightly acid; clear wavy boundary.

Cg4—40 to 48 inches; gray (5Y 5/1) loamy fine sand; single grain; loose; slightly acid; gradual wavy boundary.

Cg5—48 to 54 inches; gray (5Y 5/1) very fine sandy loam; massive; very friable; slightly acid; gradual wavy boundary.

Cg6—54 to 72 inches; gray (5Y 5/1) stratified fine and medium sand; single grain; loose; slightly acid.

Gravel, by volume, ranges from 0 to 15 percent in the particle-size control section and from 0 to 45 percent below. The soil ranges from extremely acid to slightly acid in the O, A, and E horizon and from very strongly acid to slightly acid in the C horizon.

The Oe horizon is neutral or has hue of 5YR to 5Y, value of 2 to 3, and chroma of 0 to 2. Some pedons have an Oa and/or an Oi horizon.

The A horizon, where present, has hue of 5YR to 5Y, value of 2 to 4, and chroma of 1 or 2. Texture is sand, fine sand, loamy sand, loamy fine sand, sandy loam or fine sandy loam or their mucky analogues. Structure is weak or moderate fine or medium granular or the horizon is single grain. Consistence is friable or very friable.

Some pedons have an Eg horizon that is neutral or has hue of 10YR to 5Y, value of 4 to 7, and chroma of 0 or 1. Texture is sand, fine sand, loamy sand, loamy fine sand, sandy loam or fine sandy loam.

The Cg horizon is neutral or has hue of 10YR to 5Y, value of 4 to 6, and chroma of 0 to 4. Chroma of 3 or 4 is generally below a depth of 30 inches. Redoximorphic features are faint to prominent, few to many, and fine to coarse, or may be absent. The C horizon is loamy fine sand, loamy sand, fine sand, sand or coarse sand in the fine-earth fraction and some pedons are stratified.

Correlation Note: The SeA and 367A map units have components with textures below 40 inches that are finer than typical for the range of the Searsport series. This should not significantly affect use and management on a local basis for most purposes.

Skerry Series

The Skerry series consists of very deep, moderately well drained soils on footslopes of glaciated mountains, hills, and ridges, and on till plains in the Adirondack Upland. Skerry soils formed in loamy sediments underlain by compact, very firm lodgment till. Slopes range from 3 to 15 percent.

Skerry soils are associated on the landscape with Becket, Tunbridge, Adirondack, Tahawus, Burnt Vly, Adams, and Monadnock soils. Becket soils are well drained. Tunbridge soils are 20 to 40 inches deep over meta-igneous bedrock. Adirondack soils are somewhat poorly drained. Tahawus soils are sandy and very poorly drained. Burnt Vly soils are mucky and very poorly drained. Adams soils are sandy and somewhat excessively drained. Monadnock soils are loamy over sandy or gravelly and are well drained.

Typical pedon of Skerry loam, 8 to 15 percent slopes, very bouldery, in a forested area, in the town of Minerva, 300 feet east of a point on Longs Hill Road that is 2,300 south from the junction of Longs Hill Road and O’Neil road; USGS Schroon Lake 15 minute topographic quadrangle; NAD 1927; lat. 43 degrees 47 minutes 33 seconds N. and long. 73 degrees 56 minutes 58 seconds W.

Oi—0 to 2 inch; slightly decomposed leaf, needle, and twig material.

A—2 to 4 inches; black (5YR 2.5/1) loam, moderate fine granular structure; very friable; common fine and very fine and few medium roots; 5 percent rock fragments; strongly acid; clear wavy boundary.

E—4 to 5 inches, gray (7.5YR 6/1) fine sandy loam; weak fine granular structure; very friable; common fine and very fine and few medium roots; 5 percent rock fragments; very strongly acid; clear irregular boundary.

Bhs—5 to 9 inches, dark reddish brown (5YR 3/2) fine sandy loam; weak fine and medium subangular blocky structure; friable; common fine and very fine and few medium roots; 5 percent rock fragments; very strongly acid; clear wavy boundary.

Bs—9 to 15 inches, dark reddish brown (5YR 3/4) fine sandy loam; weak medium subangular blocky structure; friable; few fine and medium roots; 10 percent rock fragments; strongly acid; clear wavy boundary.

BC1—15 to 26 inches, dark yellowish brown (10YR 4/4) gravelly fine sandy loam; weak medium and coarse subangular blocky structure; friable; 15 percent rock fragments; few fine faint reddish brown (5YR 4/4) masses of iron accumulation in lower part; moderately acid; abrupt wavy boundary.

BC2—26 to 38 inches, olive brown (2.5Y 4/3) gravelly fine sandy loam; moderate medium platy structure; firm; 15 percent rock fragments; common medium prominent yellowish red (5YR 4/6) masses of iron accumulation and distinct gray (10YR 6/1) depletions; moderately acid; clear wavy boundary.

Cd—38 to 72 inches, grayish brown (2.5Y 5/2) gravelly loamy fine sand; massive with medium and thick-plate like divisions; firm and brittle; 20 percent rock fragments; common medium prominent yellowish red (5YR 4/6) masses of iron accumulation on surfaces of plate-like divisions; moderately acid.

The thickness of the solum and depth to densic materials ranges from 15 to 38 inches. Rock fragments range from 5 to 30 percent in the solum and from 5 to 40 percent in the substratum. Unless the soil is limed, reaction ranges from extremely acid to slightly acid in the solum and very strongly acid to neutral in the substratum. Weak cementation (ortstein) ranges from 0 to 50 percent in the spodic horizon.

The 0 horizon is neutral or has hue of 2.5YR to 10YR, value of 2 to 4, and chroma of 0 to 4.

Some pedons have an A horizon up to 4 inches thick that has hue of 10YR to 5YR, value of 2 to 3, and chroma of 1 or 2, or an Ap horizon that has hue of 10YR, value of 3 or 4, and chroma of 2 to 4. Texture is fine sandy loam, sandy loam, or loam or their gravelly analogues.

The E horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 1 or 2. Texture is fine sandy loam or sandy loam or their gravelly analogues.

The Bhs or Bh horizon has hue of 2.5YR to 7.5YR, value of 2 to 4, and chroma of 1 to 4. Texture is dominantly fine sandy loam, but includes sandy loam or their gravelly analogues.

The Bs horizon has hue of 2.5YR to 10YR, value of 2 to 6, and chroma of 3 to 8. Texture is fine sandy loam or sandy loam, or their gravelly analogues.

The BC horizon, where present, has hue of 10YR to 5Y, value of 3 to 6, and chroma of 2 to 6. Texture is fine sandy loam, sandy loam, loamy fine sand, loamy sand, or their gravelly analogues.

Some pedons have an E' horizon below the B horizon that is up to 2 inches thick. It has hue of 10YR to 5Y, value of 4 to 6, and chroma of 2 or 3. Texture range is the same as the lower part of the B, but typically it is coarser textured than the overlying horizon.

The Cd horizon has hue of 10YR to 5Y, value of 4 to 7, and chroma of 2 to 6. It is comprised of loamy layers and sandy lenses with a composite texture of loamy sand, loamy fine sand, fine sandy loam, sandy loam, or their gravelly analogues. The lenses range from loamy fine sand to coarse sand and are 1/8 inch to 2 inches thick. They constitute more than 20 percent of the horizon. The Cd horizon has weak or moderate, thin to thick plates or it is massive. Consistence is firm or very firm except in individual lenses where it is friable to loose.

Some pedons have a friable C horizon above the Cd that is up to 8 inches thick.

Skylight series

The Skylight series consists of shallow, somewhat excessively drained and excessively drained sandy soils on summits, shoulders, and backslopes of glaciated mountains in the Adirondack High Peaks Area. These soils formed in sandy materials deposited by glacial ice or sandy residuum, and are underlain by meta-igneous bedrock. Slope ranges from 15 to 80 percent.

Skylight soils are associated on the landscape with Andic Cryaquods, Esther, Ricker, Santanoni, Couchsachraga, and Wallface soils. Andic Cryaquods soils are loamy, very deep, and somewhat poorly drained. Esther soils are loamy, very deep, and moderately well drained. Santanoni soils are sandy and gravelly and moderately deep to meta-igneous bedrock. Wallface soils are loamy, moderately deep to meta-igneous bedrock, and well drained. Couchsachraga soils are very shallow to meta-igneous bedrock. Ricker soils formed from organic material, are very shallow or shallow to meta-igneous bedrock, and well drained to excessively drained.

Typical pedon of Skylight loamy sand, in a map unit of Ricker-Couchsachraga-Skylight complex, 35 to 80 percent slopes, very rocky, very bouldery, in the town of Keene, approximately 1/2 mile east on the Mt. Colden trail from Lake Colden, at 3,500 feet elevation; USGS Mt. Marcy, NY topographic quadrangle; NAD 1927; lat. 44 degrees 07 minutes 20 seconds N. and long. 73 degrees 58 minutes 08 seconds W.

Oe—0 to 2 inches; dark reddish brown (5YR 2.5/2) moderately decomposed (hemic) plant material comprised of needles, leaves and twigs; weak fine granular structure; very friable; common fine and medium and few coarse roots; extremely acid; gradual wavy boundary.

Oa—2 to 5 inches; black (5YR 2.5/1) highly decomposed (sapric) plant material; weak fine granular structure; very friable; common fine and medium, and few coarse

roots; extremely acid; abrupt wavy boundary. (Combined thickness of the O horizon is 2 to 20 inches.)

E—5 to 9 inches; dark gray (5YR 4/1) loamy sand; few medium prominent yellowish red (5YR 4/6) mottles; weak medium subangular blocky structure; friable; few fine, medium and coarse roots; 1 percent rock fragments (mostly pebbles); extremely acid; clear wavy boundary (1 to 4 inches thick).

Bhs—9 to 15 inches; black (5YR 2.5/1) loamy sand; weak medium subangular blocky structure; friable, moderately smeary; common fine and medium and few coarse roots; 1 percent rock fragments (mostly pebbles); extremely acid; abrupt wavy boundary (4 to 15 inches thick).

R—15 inches; Marcy anorthosite bedrock.

The thickness of the mineral solum and depth to bedrock from the mineral soil surface ranges from 10 to 20 inches. Rock fragment content ranges from 0 to 35 percent by volume throughout the mineral solum. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. It is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) material. It has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The E horizon has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand, or coarse sand in the fine-earth fraction. It has weak fine or medium granular or subangular blocky structure, or is single grain. Consistence is very friable, friable, or loose.

The Bhs horizons and Bh horizons (where present), have hue of 10R to 7.5YR, with value and chroma of 3 or less. Texture is loamy fine sand, loamy sand, loamy coarse sand, fine sand, sand, or coarse sand in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse granular or subangular blocky structure, or are single grain. Consistence is very friable, friable, or loose. Consistence is moderately or strongly smeary.

Some pedons have a Bs horizon that has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. Texture is loamy fine sand, loamy sand, loamy coarse sand, sand or coarse sand in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, or are single grain. Consistence is very friable, friable, or loose.

Bedrock is anorthositic gneiss (metamorphosed anorthosite).

Stafford Series

The Stafford series consists of very deep, somewhat poorly drained soils on deltas and beach ridges in the Champlain Valley. Stafford soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 3 percent.

Stafford soils are associated on the landscape with Windsor, Deerfield, Gougeville, Cosad, Kingsbury, and Massena soils. Windsor soils are excessively drained. Deerfield soils are moderately well drained. Gougeville soils are poorly drained. Cosad soils are sandy over clayey. Kingsbury soils are clayey. Massena soils are loamy.

Typical pedon of Stafford fine sandy loam, 0 to 3 percent slopes, in an abandoned corner of a corn field, in the town of Willsboro, NY, 1,100 feet east of a point on Middle Road, that is 3,300 feet south of the junction of Middle Road and West Road; USGS Willsboro 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 20 minutes 58 seconds N. long. 73 degrees 23 minutes 12 seconds W.

Ap—0 to 10 inches, very dark grayish brown (10YR 3/2) fine sandy loam; light

brownish gray (10YR 6/2) dry; moderate fine and medium granular structure; friable; common fine and very fine and few medium roots; neutral (limed); abrupt smooth boundary.

Bw—10 to 20 inches, 60 percent pale olive (5Y 6/3) and 40 percent olive gray (5Y 4/2) loamy sand; weak medium subangular blocky structure; friable; common fine prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Bg—20 to 32 inches, 70 percent gray (10YR 6/1) and 30 percent yellowish brown (10YR 5/4) loamy sand; weak medium subangular blocky structure; friable; common medium prominent strong brown (7.5YR 4/6) areas of iron accumulation, and common medium faint gray (10YR 5/1) areas of iron depletion; neutral; clear smooth boundary.

Cg—32 to 72 inches, gray (10YR 6/1) sand; single grain; loose; common medium prominent yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral.

The thickness of the solum ranges from 25 to 40 inches. Depth to bedrock is greater than 60 inches. Rock fragments are typically absent, but up to 15 percent fine gravel is present in the C horizon of some pedons. Unless the soil is limed, reaction ranges from very strongly acid to neutral in the A horizon, extremely acid to slightly acid in the B horizon and strongly acid to slightly acid in the C horizon.

The Ap horizon has hue of 10YR, value of 3 or 4, and chroma of 2 or 3. Texture is fine sandy loam, loamy fine sand or fine sand. Structure is granular and consistence is friable or very friable.

The B horizon has hue of 5YR to 5Y, value of 5 or 6, chroma of 1 to 4, and contains redoximorphic features. At least one subhorizon within 20 inches has a chroma of 2. Texture is loamy sand, loamy fine sand, or fine sand. It has weak granular, subangular blocky, or platy structure or it is massive. The horizon is friable, very friable, or loose. Thin lamellae, more firm than the matrix, are present in the B horizons of some pedons.

The C horizon is neutral, or has hue of 5YR through 5Y, value of 3 through 6, and chroma of 0 or 3. It is fine sand to sand. It is massive or single grain. Consistency is friable to loose.

Correlation Note: The StA map unit has reaction in the lower part that is slightly out of the range of the Stafford series. This should not significantly affect use and management on a local basis for most purposes.

Sun Series

The Sun series consists of very deep, poorly drained soils on toeslopes of glaciated ridges and hills and on till plains in the Champlain Valley. Sun soils formed in loamy sediments underlain by firm, calcareous lodgment till. Slopes range from 0 to 3 percent.

Sun soils are associated on the landscape with Pittsfield, Nellis, Georgia, Amenia, Massena, Chatfield, and Hollis soils. Pittsfield and Nellis soils are well drained. Georgia and Amenia soils are moderately well drained. Massena soils are somewhat poorly drained. Chatfield and Hollis soils are well drained and are 20 to 40 inches deep and 10 to 20 inches deep to meta-igneous bedrock respectively.

Typical pedon of Sun silt loam, 0 to 3 percent slopes, in the town of Essex, 2,600 feet east on Stowersville Road from the intersection with Valley Road, then 800 feet south of Stowersville Road, in a field; USGS Willsboro, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 18 minutes 09 seconds N. and long. 73 degrees 28 minutes 00 seconds west longitude.

Oe—0 to 3 inches, moderately decomposed root and litter material; weak medium granular structure; very friable; many fine and very fine, and common medium roots; slightly acid; clear wavy boundary.

Ap—3 to 11 inches, black (10YR 2/1) silt loam, gray (10YR 6/1) dry; moderate fine and medium granular structure; friable; common fine and few medium roots; 5 percent rock fragments; slightly acid; abrupt wavy boundary.

Bg1—11 to 15 inches, grayish brown (2.5Y 5/2) loam; moderate medium platy structure; friable; few fine roots; 10 percent rock fragments; many medium prominent yellowish brown (10YR 5/6) and common fine prominent strong brown (7.5YR 5/6) soft masses of iron accumulation (total 50 percent of the horizon); slightly acid; clear wavy boundary.

Bg2—15 to 25 inches, gray (10YR 5/1) loam; weak medium and coarse subangular blocky structure; firm; few fine roots; 10 percent rock fragments; common medium distinct dark yellowish brown (10YR 4/4) and common fine prominent strong brown (7.5YR 5/6) soft masses of iron accumulation; slightly acid; clear smooth boundary.

BCg—25 to 40 inches, gray (10YR 6/1) gravelly fine sandy loam; weak medium and coarse subangular blocky structure; friable; 15 percent rock fragments; common medium and coarse prominent yellowish brown (10YR 5/6) and common fine and medium prominent strong brown (7.5YR 5/8) soft masses of iron accumulation; neutral; clear wavy boundary.

Cd—40 to 54 inches, grayish brown (2.5Y 5/2) gravelly sandy loam; massive with moderate thick plate-like divisions; very firm, brittle; 15 percent rock fragments; gray (10YR 5/1 plate exteriors), common medium prominent yellowish brown (10YR 5/6) soft masses of iron accumulation; slightly alkaline, slightly effervescent; gradual wavy boundary.

C—54 to 72 inches, grayish brown (2.5Y 5/2) gravelly sandy loam; massive with moderate thick plate-like divisions; firm; 15 percent rock fragments; few fine prominent light olive brown (2.5Y 5/6) soft masses of iron accumulation; moderately alkaline, strongly effervescent.

The thickness of the solum ranges from 20 to 40 inches. Depth to bedrock is greater than 60 inches. Depth to carbonates usually ranges from 20 to 70 inches however, some pedons lack carbonates. Rock fragments range in volume from 0 to 35 percent in the solum and from 15 to 50 percent in the substratum, but average less than 35 percent in the control section. These percentages include up to 10 percent greater than 3 inches in the A horizon and up to 15 percent in the B and C horizons. Reaction ranges from strongly acid through neutral in the mineral surface layer, from moderately acid through slightly alkaline in the subsoil, and from neutral to moderately alkaline in the substratum.

The Ap horizon has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 or 2. Texture of the fine-earth fraction is silt loam, loam, fine sandy loam, or sandy loam. Structure is weak or moderate, granular or subangular blocky. Consistence is friable or very friable. In uncultivated areas, the soil may have an O horizon up to 4 inches thick.

Some pedons have an E or BE horizon. They have hue of 5YR o 5Y, value of 3 through 5, and chroma of 2 to 4. Texture of the fine-earth fraction is silt loam, loam, fine sandy loam, or sandy loam in the fine-earth fraction. Structure is weak or moderate angular or subangular blocky, platy, or the horizon is massive. Consistence is friable or firm.

The Bg horizon, if present, is neutral or has hue of 10YR to 5Y, or is gley, value of 4 to 6, and chroma of 0 to 2 with chroma restricted to 0 or 1 if the horizon is massive. Redoximorphic concentrations are common or many. The Bg horizon may be absent in pedons having depleted ped face colors. Texture of the fine-earth fraction is silt loam, loam, fine sandy loam, or sandy loam. Structure is weak or moderate angular, subangular blocky, platy, or the horizon is massive. Consistence is friable or firm.

Some pedons have a Bw horizon, it has hue of 5YR to 5Y, or is gley, value of 3 to 5, and chroma of 2 to 4. It contains both areas of iron oxide accumulations and areas of iron depletions. Texture of the fine-earth fraction is sandy loam, fine sandy loam, silt loam, or loam. Structure and consistence are the same as the Bg.

The BC or BCg horizon, if present, has a hue of 5YR to 5Y, value of 3 to 6, and chroma of 1 to 4. Texture of the fine-earth fraction is sandy loam, fine sandy loam, or loam. Structure is subangular blocky, platy, or the horizon is massive. Consistence is friable or firm. Carbonates are present in some pedons.

The Cd horizon has hue of 5YR to 5Y, or is gleyed with hue of 5G, 5GY or 5BG, value is 3 to 6, and chroma of 1 to 4. Texture of the fine-earth fraction is loam, fine sandy loam, or sandy loam. Structure is massive or has plate-like divisions. Consistence is firm or very firm.

Correlation Note: The Sun SuA map unit has a firm C horizon below the Cd that is not within the range of the Sun series. This should not significantly affect the use and management on a local basis.

Sunapee Series

The Sunapee series consists of very deep, moderately well drained soils on footslopes of glaciated hills and ridges and on till plains in the Adirondack Upland. These soils formed in friable loamy sediments deposited by glacial ice. Slopes range from 3 to 15 percent.

Sunapee soils are associated on the landscape with Monadnock, Adirondack, Tahawus, Tunbridge, Croghan, Fernlake, Becket, and Burnt Vly soils. Monadnock soils are loamy over sandy or gravelly and are well drained. Adirondack soils have a dense substratum and are somewhat poorly drained. Tahawus soils are sandy and are very poorly drained. Tunbridge soils are 20 to 40 inches deep to meta-igneous bedrock and are well drained. Croghan soils are sandy. Fernlake soils are sandy and are well drained. Becket soils have a dense substratum and are well drained. Burnt Vly soils are mucky and are very poorly drained.

Typical pedon of Sunapee fine sandy loam, 3 to 8 percent slopes, in the town of North Elba, 0.8 mile East on Old Military Road from NY 86, then 300 feet North on dirt road, then 150 feet East into woods, 20 feet North of the edge of a small meadow. USGS Saranac Lake 15 minute topographic quadrangle; 44 degrees, 17 minutes, 4 seconds north latitude, and 74 degrees, 0 minutes, 36 seconds west longitude; NAD 1927.

Oe—0 to 1 inch, black (10YR 2/1) moderately decomposed forest litter.

A—1 to 4 inches, dark brown (7.5YR 3/2) fine sandy loam; weak fine granular structure; very friable; many fine and very fine and common medium roots; 5 percent rock fragments; very strongly acid; abrupt smooth boundary.

E—4 to 5 inches, brown (7.5YR 5/2) fine sandy loam; massive; very friable; common very fine, fine, and medium roots; 5 percent rock fragments; very strongly acid; abrupt wavy boundary.

Bs1—5 to 7 inches, dark brown (7.5YR 3/4) fine sandy loam; weak fine and medium subangular blocky parting to weak fine granular structure; very friable; common very fine, fine, and medium roots; 5 percent rock fragments; very strongly acid; clear broken boundary.

Bs2—7 to 14 inches, brown (7.5YR 4/4) fine sandy loam; weak fine and medium subangular blocky parting to weak fine granular structure; very friable; common fine and very fine and few medium roots; 10 percent rock fragments; very strongly acid; gradual wavy boundary.

BC1—14 to 19 inches, dark yellowish brown (10YR 4/4) fine sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and very fine roots; 10 percent rock fragments; very strongly acid; clear wavy boundary.

BC2—19 to 31 inches, brown (10YR 5/3) gravelly sandy loam; weak fine and medium subangular blocky structure; friable; few fine and very fine roots; 15 percent rock fragments; common fine prominent strong brown (7.5YR 5/6) soft masses of iron accumulation, and common medium faint grayish brown (10YR 5/2) and few fine light brownish gray faint (10YR 6/2) iron depletions in lower part; strongly acid; gradual wavy boundary.

C—31 to 72 inches, light olive brown (2.5Y 5/3) gravelly loamy sand; massive; friable; 20 percent rock fragments; few fine prominent strong brown (7.5YR 5/6) soft masses of iron accumulation, common medium and coarse faint grayish brown (2.5Y 5/2) iron depletions; strongly acid; gradual wavy boundary.

The thickness of the solum ranges from 18 to 39 inches. Distinct or prominent redoximorphic features are present above 30 inches. Rock fragments range from 5 to 35 percent in the solum and 5 to 55 percent in the substratum. Unless the soil is limed, the solum ranges from extremely acid to strongly acid and the C horizon from extremely acid to moderately acid.

Some pedons have an 0 horizon that is neutral or has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 0 to 2. The horizon has partially, moderately, or highly decomposed plant (fibric, hemic or sapric) material and is up to 5 inches thick.

The A horizon has hue 5YR to 10YR, value of 2 to 3, and chroma of 1 or 2. Some pedons have an Ap horizon that has hue of 10YR, with value and chroma of 2 to 4. The A horizon is fine sandy loam or loam or their gravelly or cobbly analogues.

The E horizon has hue 7.5YR to 2.5Y, value of 4 to 7, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or loam and their gravelly or cobbly analogues.

The Bhs horizon has hue 2.5YR to 7.5YR and value and chroma of 3 or less.

Some pedons have a Bh horizon that has hue 2.5YR to 7.5YR, value of 2 to 3, and chroma of 1 to 4.

The Bs horizon has hue 5YR to 2.5Y, value 3 to 5, and chroma 3 to 6. Texture is fine sandy loam or sandy loam or their gravelly or cobbly analogues. Consistence is friable or very friable when moist, but ranges from soft to hard when dry.

Some pedons have a BC horizon that has hue 7.5 YR to 5Y, value 4 to 6, and chroma 2 to 6. Texture is fine sandy loam or sandy loam or their gravelly or cobbly analogues. Consistence is friable or very friable when moist, but ranges from soft to hard when dry.

The C horizon has hue 10YR to 5Y, value 4 to 6, and chroma 2 to 4. Texture is fine sandy loam or sandy loam or their gravelly or cobbly analogs. Loamy sand or loamy fine sand or their gravelly or cobbly analogues is below a depth of 30 inches in some pedons. The horizon is massive or has weak platy structure. Consistence is very friable or friable when moist, but ranges from loose to hard when dry.

Tahawus Series

The Tahawus series consists of very deep, very poorly drained soils in depressions on undulating till plains and on toeslopes of glaciated hills and ridges in the Adirondack Upland. Slopes range from 0 to 5 percent.

Tahawus soils are associated on the landscape with Adirondack, Becket, Burnt Vly, Pleasant Lake, Lyman, Monadnock, Skerry, Sunapee and Tunbridge soils. Adirondack soils are loamy and are somewhat poorly drained. Becket soils are loamy and are well drained. Burnt Vly and Pleasant Lake soils are mucky and are very poorly drained. Lyman soils are loamy and are 10 to 20 inches deep over meta-igneous bedrock. Monadnock soils are loamy over sandy and are well drained. Skerry and Sunapee soils are loamy and are moderately well drained. Tunbridge soils are loamy and are 20 to 40 inches deep over meta-igneous bedrock.

Typical pedon of Tahawus peat, in a map unit of Monadnock-Tahawus Complex, 0 to 15 percent slopes, very bouldery, in a wooded area, town of Schroon, 2,000 feet southwest (240 degree azimuth) of northwest corner of Big Pond, in depression between two small hills; USGS Schroon Lake 15 minute topographic quadrangle; NAD 1927; lat, 43 degrees 51 minutes 24 seconds N. and long. 73 degrees 49 minutes 46 seconds W.

Oi—0 to 2 inches; very dark grayish brown (2.5Y 3/2) broken face and rubbed peat (fibric material); 95 percent unrubbed fiber, 90 percent rubbed fiber; massive; very friable; many fine and few medium roots; very strongly acid; abrupt wavy boundary.

Oe—2 to 5 inches; dark reddish brown (5YR 2.5/2) broken face and rubbed mucky peat (hemic material); 70 percent unrubbed fiber, 20 percent rubbed fiber; weak thin platy structure; very friable; many fine and few medium roots; very strongly acid; clear wavy boundary.

Oa—5 to 9 inches; black (5YR 2.5/1) broken face and rubbed muck (sapric material); 10 percent unrubbed fiber, less than 1 percent rubbed fiber; weak medium subangular blocky structure; very friable; few fine roots; very strongly acid; abrupt wavy boundary.

Bg—9 to 17 inches; light brownish gray (2.5Y 6/2) sandy loam; weak medium subangular blocky structure; friable; few fine roots; 12 percent rock fragments; many medium and coarse distinct brown (10 YR 4/3) masses of iron accumulation; moderately acid; clear wavy boundary.

Cg1—17 to 24 inches; gray (2.5Y 5/1) gravelly loamy sand; massive; friable; few fine roots; 30 percent rock fragments; common medium prominent yellowish brown (10YR 5/6) masses of iron accumulation; neutral; gradual smooth boundary.

Cg2—24 to 72 inches; gray (N 5/0) gravelly loamy sand; massive; friable; 25 percent rock fragments; few medium prominent dark yellowish brown (10YR 4/6) masses of iron accumulation; neutral.

The thickness of the solum ranges from 12 to 36 inches. Depth to bedrock is greater than 60 inches. Rock fragments, mainly stones, cobbles, and gravel, range from 5 to 35 percent by volume throughout the soil. Redoximorphic features are within 20 inches of the mineral surface.

The O horizon is neutral or has hue of 5YR to 2.5Y, value of 2 to 3, and chroma of 0 to 2. The horizon is peat, mucky peat, or muck. Structure is weak granular, platy, subangular blocky, or the horizon is massive. Reaction ranges from extremely acid to strongly acid.

Some pedons have an A horizon that is neutral or has hue of 5YR to 2.5Y, value of 2 to 3, and chroma of 0 to 2. Texture is fine sandy loam, sandy loam, loamy fine sand, or loamy sand in the fine earth fraction. Structure is weak granular. Consistence is very friable. Reaction ranges from very strongly acid through slightly acid. It is 0 to 6 inches thick.

Some pedons have an E horizon that is neutral or has hue of 5YR to 2.5Y, value of 4 to 7, and chroma of 0 to 2. Texture and reaction ranges are the same as the A horizon. Structure is weak subangular blocky or the horizon is massive. Consistence is friable or very friable. The horizon is 0 to 4 inches thick.

The B horizon is neutral or has hue of 5YR to 2.5Y, value of 3 to 6, and chroma of 0 to 3. Texture is fine sandy loam, sandy loam, loamy fine sand, or loamy sand in the fine earth fraction. Structure is weak subangular blocky or the horizon is massive. Consistence is friable or very friable. Reaction ranges from very strongly acid to slightly acid.

Some pedons have a BC horizon with colors, structure, consistence and reaction similar to the B horizon. Texture is loamy fine sand, loamy sand, or sand. The horizon is 0 to 15 inches thick.

The C horizon is neutral or has hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 0 to 4. Texture is loamy fine sand, loamy sand, sand, loamy coarse sand, or coarse sand in the fine earth fraction. Thin layers of fine sandy loam or sandy loam are allowed below a depth of 40 inches from the mineral surface. The C horizon is massive or single grain. Consistence is friable or firm. Reaction ranges from moderately acid to neutral.

Tonawanda Series

The Tonawanda series consists of very deep, somewhat poorly drained soils on lake plains and lacustrine terraces in the Champlain Valley. Tonawanda soils formed in silty sediments deposited in still water. Slopes range from 0 to 3 percent.

Tonawanda soils are associated on the landscape with Niagara, Rippowam, Amenia, Massena, and Factoryville soils. Niagara soils have higher clay contents. Rippowam and Massena soils are loamy. Amenia soils are loamy and moderately well drained. Factoryville soils are sandy and well drained.

Typical pedon of Tonawanda silt loam, 0 to 3 percent slopes, in a hay field, in the town of Chesterfield, 130 feet northwest of a point on Mace Chasm Road, that is .5 miles south of the junction of Mace Chasm Road and Thompson Finney Road; USGS Willsboro, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 28 minutes 42 seconds N. and long. 73 degrees 28 minutes 00 seconds W.

Ap—0 to 9 inches, very dark grayish brown (10YR 3/2) silt loam, light brownish gray (10YR 6/2) dry; moderate fine and medium granular structure; friable; many fine and very fine and common medium roots; slightly acid; abrupt smooth boundary.

Bw—9 to 14 inches, brown (10YR 4/3) silt loam; moderate medium subangular blocky structure; friable; few very fine and fine roots; common medium faint light brownish gray (10YR 6/2) iron depletions and common medium distinct yellowish brown (10YR 5/6) soft masses of iron accumulation; slightly acid; clear smooth boundary.

Bg—14 to 22 inches, grayish brown (10YR 5/2) silt loam; weak medium subangular blocky parting to moderate medium granular structure; friable; few fine and very fine roots; many medium prominent yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral; clear smooth boundary.

Cg—22 to 72 inches, dark grayish brown (10YR 4/2) silt loam; massive with weak medium plate-like divisions; firm; common medium faint grayish brown (10YR 5/2) iron depletions and common medium prominent yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral.

The thickness of the solum ranges from 16 to 40 inches. Rock fragments range from 0 to 2 percent in the solum and 0 to 15 percent in the substratum. Reaction ranges from very strongly acid to neutral in the surface layer, strongly acid to neutral in the subsoil, and from moderately acid to slightly alkaline in the substratum. Below a depth of 40 inches from the surface, some pedons range to moderately alkaline and are effervescent.

The Ap horizon has hue of 10YR or 2.5Y, value of 2 to 4, and chroma of 1 to 3. Texture is silt loam, silt, very fine sandy loam or loam. Some pedons have a thin A horizon or AB horizon.

The B horizon has hue of 5YR to 5Y, value of 4 to 6, and chroma of 1 to 4. The matrix has a chroma of 3 or greater immediately below the A or Ap or to a depth of greater than 10 inches below the mineral surface. Texture is silt loam, loam, silt, very fine sandy loam, or loamy very fine sand. Thin layers, 1 to 3 inches thick, of sand or gravelly sand, and silty clay loam are in some pedons. Structure is weak or moderate, very fine to medium, granular or subangular blocky. Some B horizons have prismatic structure. Consistence is very friable to firm.

The C horizon has hue of 5YR to 5Y, value of 4 to 6, and chroma of 1 to 6. Texture is silt loam, loam, silt, or very fine sandy loam. Thin strata of sand to fine sandy loam or silty clay loam are in some pedons. It is massive or has plate-like divisions. Consistence is loose to firm.

Tunbridge Series

The Tunbridge series consists of moderately deep, well drained soils on summits, shoulders, and backslopes of glaciated hills, ridges, and mountains in the Adirondack Upland. Tunbridge soils formed in loamy sediments deposited by glacial ice and are underlain by meta-igneous bedrock. Slopes range from 3 to 60 percent.

Tunbridge soils are associated on the landscape with Becket, Monadnock, Lyman, Knob Lock, Adirondack, Skerry and Tahawus soils. Becket and Monadnock soils are very deep. Lyman soils are 10 to 20 inches deep to meta-igneous bedrock. Knob Lock soils are mucky and are 1 to 20 inches deep to meta-igneous bedrock. Adirondack soils are very deep and somewhat poorly drained. Skerry soils are very deep and moderately well drained. Tahawus soils are sandy, very deep, and very poorly drained.

Typical pedon of Tunbridge sandy loam, in a map unit of Tunbridge-Lyman complex, 35 to 60 percent slopes, very rocky, very bouldery, in the town of Elizabethtown, on International Paper property north of Mineville, in a road cut about 1 mile past gate; USGS Elizabethtown, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees, 7 minutes, 54 seconds N. and long. 73 degrees, 32 minutes, 8 seconds W.

Oi—0 to 1 inch, slightly decomposed forest litter; many fine and very fine roots.

Oa—1 to 3 inches, highly decomposed forest litter (sapric material); many fine and very fine and few coarse roots.

E—3 to 4 inches, dark grayish brown (10YR 4/2) sandy loam; weak fine granular structure; very friable; common very fine roots; 10 percent rock fragments; very strongly acid; abrupt smooth boundary.

Bh—4 to 7 inches, dark reddish brown (5YR 2.5/2) fine sandy loam; weak very fine granular structure; very friable; many fine and very fine few coarse roots; 10 percent rock fragments; very strongly acid; clear wavy boundary.

Bhs—7 to 13 inches, dark brown (7.5YR 3/3) fine sandy loam; weak very fine granular structure; very friable; many fine and very fine few coarse roots; 10 percent rock fragments; very strongly acid; clear wavy boundary.

Bs—13 to 18 inches, brown (7.5YR 4/4) fine sandy loam; weak fine granular structure; very friable; common fine and very fine roots; 10 percent rock fragments; very strongly acid; abrupt smooth boundary.

C—18 to 27 inches, light olive brown (2.5Y 5/4) gravelly sandy loam; massive; friable; few fine roots; 15 percent rock fragments; strongly acid.

R—27 inches, meta-igneous bedrock.

The thickness of the solum ranges from 14 to 38 inches. The depth to bedrock ranges from 20 to 40 inches. Reaction ranges from extremely acid to moderately acid in the solum and from strongly acid to slightly acid in the substratum. Rock fragments are mostly gravel, channers, and cobbles and range from 5 to 35 percent throughout the soil. The thickness of spodic horizon (Bh, Bs, and Bhs horizon, where present) ranges from 4 to 16 inches and is weakly smeary or not smeary. The silt content in the solum and substratum is typically less than 50 percent. The fine-earth is typically fine sandy loam, sandy loam, very fine sandy loam or loam, but horizons of silt loam are allowed. Stony and bouldery phases of the Tunbridge series are recognized.

Some pedons have Oi, Oe, and/or Oa horizons overlying the A horizon. Combined thickness of the O horizons is 0 to 5 inches thick.

The A horizon is neutral or has hue of 5YR to 10YR, value of 2 to 5, and chroma of 0 to 4. Texture is typically loam, very fine sandy loam, fine sandy loam or sandy loam in the fine-earth fraction but includes silt loam.

Some pedons have an Ap horizon that has hue of 5YR to 10YR, value of 2 to 4, and chroma of 2 to 4. Textures are similar to the A horizon.

The E horizon has hue of 5YR to 10YR, value of 4 to 6, and chroma of 1 or 2. Texture is typically loam, very fine sandy loam, fine sandy loam, sandy loam or loamy fine sand in the fine-earth fraction but includes loamy fine sand and silt loam.

Some pedons have a BE horizon that has hue of 5YR to 10YR, value of 4 to 6, and chroma of 2 to 4. Textures are similar to the E horizon.

The Bh horizon, where present, is neutral or has hue of 5YR to 10YR. The horizon typically has value of 2 or 3, and chroma of 0 to 2, but higher values and chromas are allowed.

The Bs horizon, where present, has hue of 5YR to 2.5Y, value and chroma of 4 or more.

Some pedons have a Bhs horizon that has hue of 5YR to 10YR, value and chroma of 3 or less. The horizon is up to 6 inches thick.

Some pedons have a BC horizon with hue of 7.5YR to 2.5Y, value of 3 to 5, and chroma of 3 to 8. The horizon is up to 12 inches thick.

The B horizons are typically loam, very fine sandy loam, fine sandy loam or sandy loam in the fine-earth fraction but includes silt loam.

The C horizon has hue of 10YR to 5Y, value of 4 to 6, and chroma of 2 to 6. Texture is typically loam, very fine sandy loam, fine sandy loam, or sandy loam in the fine-earth fraction but includes silt loam.

Bedrock is slightly weathered schist, gneiss, phyllite, or granite.

Typic Endoaquolls

Typic Endoaquolls consist of very deep, poorly drained soils formed in loamy glacial till. These soils are on depressions of glacial moraines and upland basins. Slopes range from 0 to 2 percent.

Typic Endoaquolls soils are in a drainage sequence with the well drained Pyrities soils, the moderately well drained Kalurah soils, and the somewhat poorly drained Malone soils. Other associated soils include the Nehasne, Monadnock, Tunbridge and Champlain soils. The Nehasne and Tunbridge soils are well drained and moderately deep to bedrock. Monadnock soils are well drained. Champlain soils are sandy and somewhat excessively drained.

Typical pedon of Typic Endoaquolls, in the town of Pierrepont, St. Lawrence County, 0.7 mile SW on Noyes Road from the intersection with Parmenter Road, to power line, then 170 feet SE along power line path, then 25 feet north of path in opening in brush; USGS Colton, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 44 degrees 36 minutes 22 seconds N. and long. 74 degrees 59 minutes 49 seconds W.

Ap—0 to 10 inches; very dark brown (10YR 2/2) loam, grayish brown (10YR 5/2) dry; weak medium and fine granular structure; very friable; common fine and medium roots; 5 percent rock fragments (gravels and cobbles); slightly acid; clear wavy boundary.

Bg1—10 to 15 inches; grayish brown (10YR 5/2) sandy loam; weak fine subangular blocky structure; friable; few fine roots; 12 percent rock fragments (gravels and cobbles); common medium faint light brownish gray (10YR 6/2) areas of iron depletion, few fine prominent yellowish brown (10YR 5/8) and common medium distinct yellowish brown (10YR 5/4) areas of iron accumulation; neutral; clear wavy boundary.

Bg2—15 to 24 inches; grayish brown (10YR 5/2) sandy loam; weak thick platy parting to weak medium subangular blocky structure; friable; 12 percent rock fragments (gravels and cobbles); common medium distinct dark yellowish brown (10YR 4/4) and common medium faint brown (10YR 5/3) areas of iron accumulation (some plate faces are light brownish gray (10YR 6/2)); neutral; clear wavy boundary;

C—24 to 72 inches; grayish brown (10YR 5/2) sandy loam; massive; friable; 12 percent rock fragments (gravels and cobbles); common medium faint gray (10YR 6/1) areas of iron depletion, and common medium distinct yellowish brown (10YR 5/4) and common fine prominent strong brown (7.5YR 5/6) areas of iron accumulation; slightly alkaline, slightly effervescent.

Depth to free carbonates ranges from 17 to 36 inches. Rock fragments of mixed lithology comprise 3 to 15 percent of the volume of the series control section and C horizon but in some pedons rock fragment range to 20 percent in the C horizon. The mollic epipedon ranges from 8 to 20 inches in thickness. The series control section averages between 8 to 18 percent clay and 50 to 70 percent sand. Some pedons have an 0 horizon less than 4 inches thick.

The A horizon has hue of 10YR to 5Y, or is neutral, value of 2 or 3, and chroma of 1 to 2. It has redoximorphic features in some pedons. Texture is sandy loam, fine sandy loam, loam, or its mucky modifier. Reaction is slightly acid or neutral.

The B horizon has hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 or 2. Some pedons have chroma of 3 in the lower part. It has faint to prominent redoximorphic features in all parts. Texture is sandy loam, or loam. Reaction is slightly acid to slightly alkaline. A BC horizon is in some pedons.

The C or Cg horizon has hue of 10YR to 5Y, value of 5 or 6, and chroma of 1 to 3. It has faint to prominent redoximorphic features. Reaction is slightly acid to moderately alkaline. The horizon has 6 to 20 percent calcium carbonate equivalent.

Correlation Note: The TeA map unit is at the Taxon above Family. It was intended to be the Runeberg series. While it fits the classification of the Runeberg series, the properties of the Minnesota based series do not fit the Essex County climate, elevation, water table, and permeability.

Udifluvents

Udifluvents consist of very deep, excessively drained to moderately well drained soils formed in alluvium recently deposited by streams. Udifluvents are on the most actively flooded areas of the flood plain along major and secondary streams in the county. Sediments are typically loamy, sandy, or sandy skeletal. Slopes range from 0 to 3 percent. Udifluvents are in areas of the flood plain immediately adjacent to streams. Scouring, cutting, lateral erosion, changing stream channels and redeposition of sediments during frequent flooding are responsible for the variability in composition and properties of Udifluvents.

Udifluvents occur in a complex with the somewhat poorly drained to very poorly drained Fluvaquents soils, and are mapped in both the frigid and mesic areas of the county. They are commonly near Ondawa, Occum, Podunk, Pootatuck, Lovewell, Cornish, Rumney, Rippowam, Charles, Medomak, and Burnt Vly soils. The frigid Ondawa and mesic Occum soils are well drained. The frigid Podunk and mesic Pootatuck soils are moderately well drained. The frigid Rumney and mesic Rippowam soils are poorly drained. The frigid Burnt Vly soils are organic over sandy and are very poorly drained. The frigid and moderately well drained Lovewell, somewhat poorly drained Cornish, poorly drained Charles, and very poorly drained Medomak soils are silty.

Although these soils are highly variable, an example of the loamy phase is provided here. Pedon of Udifluvents, in a map unit of Fluvaquents-Udifluvents complex, frequently flooded, 0 to 3 percent slopes in a wooded area, in the town of Elizabethtown, Elizabethtown Fish & Game Club Property, 1,400 feet north of the junction of the club road and the Elizabethtown-Wadhams road; USGS Elizabethtown 15 minute topographic quadrangle; NAD 1983; lat. 44 degrees 13 minutes 54.5 seconds N. and long. 73 degrees 34 minutes 14.3 seconds W.

C—0 to 4 inches, light olive brown (2.5Y 5/3) loamy fine sand; single grain; loose; common fine and very fine, and few medium roots; neutral; abrupt wavy boundary.

Ab—4 to 6 inches, very dark gray (2.5Y 3/1) fine sandy loam; weak fine granular structure; very friable; many fine and very fine, and common medium roots; slightly acid; abrupt wavy boundary.

Cb—6 to 10 inches, 80 percent olive brown (2.5Y 4/3) and 20 percent very dark olive brown (2.5Y 3/3) fine sandy loam; massive; very friable; common fine and very fine, and few medium roots; slightly acid; abrupt wavy boundary.

A’b—10 to 12 inches, very dark grayish brown (10YR 3/2) fine sandy loam; weak fine granular structure; very friable; common fine and very fine, and few medium roots; slightly acid; abrupt wavy boundary.

C’b—12 to 24 inches, 60 percent dark brown (10YR 3/3) and 40 percent light olive brown (2.5Y 5/3) fine sandy loam; massive; friable; common fine and very fine, and few medium roots; slightly acid; abrupt wavy boundary.

A”b—24 to 28 inches, very dark grayish brown (2.5Y 3/2) fine sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and very fine, and few medium roots; moderately acid; abrupt wavy boundary.

C”b—28 to 34 inches, 70 percent olive brown (2.5Y 4/3) and 30 percent very dark grayish brown (2.5Y 3/2) loamy fine sand; single grain; loose; common fine and medium, and few coarse roots; moderately acid; abrupt wavy boundary.

A’”b—34 to 38 inches, very dark grayish brown (10YR 3/2) fine sandy loam; weak fine and medium subangular blocky structure; very friable; common fine and medium, and few coarse roots; moderately acid; abrupt wavy boundary.

C1—38 to 44 inches, 70 percent olive brown (2.5Y 4/3) and 30 percent very dark grayish brown (2.5Y 3/2) fine sandy loam; massive; friable; common fine and medium, and few coarse roots; moderately acid; clear wavy boundary.

C2—44 to 56 inches, dark olive brown (2.5Y 3/3) fine sandy loam; massive; friable; common fine and medium, and few coarse roots; moderately acid; abrupt wavy boundary.

C3—56 to 72 inches, variegated but dominantly dark brown (10YR 3/3) very gravelly coarse sand; single grain; loose; 50 percent gravel; moderately acid.

Generally the surface layer is 3 to 15 inches thick. The depth to bedrock is more than 60 inches.

The surface layer has hue of 10YR to 5Y, value of 3 to 5, and chroma of 1 to 6. Texture is very fine sandy loam to coarse sand, and their gravelly or very gravelly analogs. Rock fragments range from 0 to 70 percent. Reaction is strongly acid to neutral.

The substratum has hue of 10YR to 5Y, value of 3 to 5, and chroma of 1 to 6. Some pedons have redoximorphic features below 20 inches. Texture is very fine sandy loam through coarse sand, and their gravelly or very gravelly analogs. Structure is massive. Rock fragments range from 0 to 70 percent. Reaction is strongly acid to neutral.

Correlation Note: Included in the FuA map unit are some areas of frigid soils. This should not affect use and management of this map unit.

Udorthents

Udorthents consist of very deep, excessively drained to somewhat poorly drained soils or soil material on small to large man-made hills adjacent to inactive open pit and shaft mining operations, or on small closed landfills, reclaimed industrial sites, borrow pits, or construction sites throughout the county. Udorthents material consists of pulverized rock debris that is a result of ore mining, processing, and deposition by man, or this is local soil material sometimes mixed with, and overlies construction and

demolition debris and/or refuse. In many cases, silty or loamy soil material brought in from another source and spread for reclamation purposes overlies the disturbed material. Slopes range from 0 to 60 percent.

Included and associated soils are highly variable, and reflect the location in the county and soils directly adjacent to the disturbed areas. Mine spoil, abandoned landfill, sand and gravel pits, and abandoned industrial sites are commonly reclaimed at least in part by soil material found near the site. Reclamation material may be sandy, loamy, or clayey. These soils are named above the series level in the soil classification system because of variability in the material and a lack of soil features that would permit more detailed classification.

Typical pedon of Udorthents, 0 to 60 percent slopes, on an excessively drained man-made terrace reclaimed from mine spoil and planted to mixed grasses, in the town of Newcomb, 2,000 feet east of bridge across Hudson River to McIntyre Development, on first terrace above, and just west of entry road; USGS Santanoni, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 02 minutes 36 seconds N. and long. 74 degrees 03 minutes 04 seconds W.

A—0 to 5 inches; dark brown (10YR 3/3) silt loam; weak fine and medium granular structure; friable; many fine and very fine roots; 2 percent gravel; slightly acid; clear smooth boundary.

C—5 to 9 inches; yellowish brown (10YR 5/4) silt loam; massive with weak thin plate-like divisions; friable; common very fine and few fine roots; 2 percent gravel; slightly acid; abrupt smooth boundary.

2C—9 to 72 inches; dark gray (10YR 4/1) extremely gravelly loamy sand; single grain; loose; 60 percent gravel, 20 percent cobbles, 5 percent stones; neutral.

The thickness of the solum generally ranges from 0 to 20 inches. Depth to bedrock is typically greater than 72 inches. Rock fragments are highly variable in the reclamation material if present, but are typically less than 20 percent by volume. Rock fragments in the mine spoil material are typically greater than 35 percent by volume. Fill material underlying old industrial or urban sites range from 0 to 70 percent rock fragments by volume and can include construction and demolition debris as well as local geologic sources.

The A horizon, where present, typically has hue of 7.5YR to 5Y, and value and chroma of 2 or 3. Texture is typically dependent on the source of the reclamation material or the surface texture of the spoil or fill material and is highly variable, but typically ranges from clay to coarse sand in the fine earth fraction. Reaction typically ranges from moderately acid to slightly alkaline.

The C horizon, where present, typically has hue of 7.5YR to 5Y, value of 4 or more, and chroma of 1 or more. Texture is typically dependent on the source of the reclamation material or local fill material, and is highly variable, but typically ranges from clay to coarse sand. Reaction typically ranges from moderately acid to neutral.

The 2C horizon, or C horizon if there has been no reclamation efforts, typically has hue of 7.5YR to 5Y, value of 3 or more, and chroma of 1 or more. Texture typically ranges from loamy sand to coarse sand for mine spoil in the fine earth fraction, clay to coarse sand for reclaimed borrow, sand, gravel, and industrial site areas, and layers of refuse and other buried waste material in old landfill sites. Reaction typically ranges from slightly acid to strongly alkaline.

Vergennes Series

The Vergennes series consists of very deep, moderately well drained soils on lake plains in the Champlain Valley. Vergennes soils formed in clayey sediments deposited in still water that was fresh or brackish. Slopes range from 3 to 45 percent (fig. 46).

Figure 46.—Soil profile of the Vergennes series from a road cut, in the town of Westport, on the edge of a hay field. Note the well developed angular blocky structure in the upper subsoil, coarse prismatic structure in the lower subsoil, and depositional lamination in the dark brown substratum. This soil has very high clay content, but is a good agricultural soil if managed properly. It has high native fertility and good available water, but tillage can be a problem on these soils. Because of the high clay content, very slow internal drainage, and high shrink-swell potential, this soil presents serious problems for most residential uses.

Vergennes soils are associated on the landscape with Kingsbury, Covington, Livingston, Cayuga, Amenia, Charlton, Chatfield, and Farmington soils. Kingsbury soils are somewhat poorly drained. Covington soils are poorly drained. Livingston soils are very poorly drained. Cayuga soils are clayey over loamy. Amenia soils are loamy. Charlton soils are loamy and well drained. Chatfield soils are loamy, well drained, and are 20 to 40 inches deep to meta-igneous bedrock. Farmington soils are loamy, well drained, and are 10 to 20 inches deep to limestone bedrock.

Typical pedon of Vergennes silty clay loam, 3 to 8 percent slopes, in a corn field, in the town of Crown Point, NY; 50 feet north of the point on Burdick Road located 1 mile east of the junction of Burdick Road and State Route 9N; USGS Crown Point 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 59 minutes 08 seconds N. and long. 73 degrees 26 minutes 13 seconds W.

Ap—0-8 inches, dark grayish brown (10YR 4/2) silty clay loam; weak medium and coarse subangular blocky structure parting to weak fine granular; friable; slightly sticky and slightly plastic; common fine and medium and few coarse roots; neutral; abrupt smooth boundary.

B/E—8-10 inches, 88 percent brown (10YR 5/3) and 12 percent grayish brown (10YR 5/2) clay; weak fine subangular blocky structure; friable; moderately sticky and plastic; common fine and medium roots; common fine vesicular and few fine tubular pores; very thin discontinuous clay films in pores; many fine and medium prominent yellowish brown (10YR 5/6) soft masses of iron accumulation; neutral; clear wavy boundary.

Bt—10-22 inches, brown (10YR 4/3) clay; ped surfaces are brown (10YR 5/3); moderate fine and medium subangular blocky structure; friable; very sticky and

very plastic; common fine and medium and few coarse roots; many fine vesicular and few fine and medium tubular pores; thin discontinuous clay films on ped surfaces and pore linings; common fine and medium distinct dark yellowish brown (10YR 4/6) soft masses of iron accumulation and few fine faint light brownish gray (10YR 6/2) iron depletions in lower part; neutral; clear smooth boundary.

BC—22-29 inches, 50 percent dark grayish brown (10YR 4/2) and 50 percent brown (10YR 4/3) silty clay; weak very coarse prismatic parting to moderate fine and very fine subangular blocky structure; friable; very sticky and very plastic; few fine, medium and coarse roots; many fine vesicular and few fine and medium tubular pores; thin discontinuous clay films on ped surfaces; common fine prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; ped surfaces are grayish brown (10YR 5/2); slightly alkaline, slightly effervescent; gradual wavy boundary.

C1—29-37 inches, 50 percent dark grayish brown (10YR 4/2) and 50 percent brown (10YR 4/3) silty clay; weak coarse prismatic structure parting to moderate fine and medium angular blocky; firm, very sticky and very plastic; few fine and medium coarse roots; common fine vesicular and few fine tubular pores; common coatings of light gray (10YR 7/2) CaCO3 on prism surfaces; common fine prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; ped surfaces are gray (10YR 5/1); moderately alkaline, strongly effervescent; gradual wavy boundary.

C2—37-45 inches, brown (10YR 4/3) silty clay; weak coarse prismatic structure parting to weak fine and medium angular blocky; firm, very sticky and very plastic; few fine roots; 2 percent pebbles; common fine vesicular and few fine tubular pores; common light gray (10YR 7/2) nodules of CaCO3; few medium faint dark yellowish brown (10YR 4/4) soft masses of iron accumulation; ped surfaces are gray (10YR 6/1); moderately alkaline, strongly effervescent; gradual wavy boundary.

C3—45-77 inches, variegated grayish brown (10YR 5/2) gray (5Y 5/1) and brown (10YR 4/3) clay; moderate very coarse prismatic structure parting to moderate coarse angular blocky; firm, very sticky and very plastic; few fine roots; 2 percent pebbles; few fine vesicular and tubular pores; light gray (10YR 7/2) carbonate nodules; few fine prominent dark yellowish brown (10YR 4/6) soft masses of iron accumulation; ped surfaces are gray (10YR 5/1); moderately alkaline, strongly effervescent.

The thickness of solum ranges from 14 to 40 inches. Depth to bedrock is greater than 60 inches. Rock fragments range from 0 to 2 percent. Reaction ranges from very strongly acid to neutral in the upper part of the solum and moderately acid to slightly alkaline in the lower part. The C horizon is moderately alkaline. Depth to free carbonates ranges from 18 to 40 inches.

The Ap horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 1 to 4. The A horizon is clay, silty clay, silty clay loam, or silt loam.

Some pedons have an E horizon which has hue of 7.5YR to 2.5Y, value of 5 or 6, and chroma of 2 or 3. The E horizon is clay, silty clay, silty clay loam, or silt loam.

The B/E horizon has colors and textures similar to the Bt and E horizons.

The Bt horizon has hue of 7.5YR to 5Y, value of 3 to 5, and chroma of 1 to 4. Texture is clay.

Some pedons have a BC horizon.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 5, and chroma of 1 to 4. Texture is clay with silt and silty clay varves.

Wallface Series

Wallface soils consist of moderately deep, well drained soils on summits, shoulders, and backslopes of glaciated mountains in the Adirondack High Peaks Area. These soils

formed in loamy materials deposited by glacial ice, and are underlain by meta-igneous bedrock. Slopes range from 15 to 35 percent.

Wallface soils are associated on the landscape with Andic Cryaquods, Couchsachraga, Ricker, Esther, Skylight, and Santanoni soils. Andic Cryaquods soils are very deep and somewhat poorly drained. Couchsachraga soils are sandy, very shallow to bedrock, and somewhat excessively drained and excessively drained. Ricker soils are organic, shallow or very shallow to bedrock, and are well drained to excessively drained. Esther soils are very deep and moderately well drained. Skylight soils are sandy, moderately deep to bedrock, and somewhat excessively drained and excessively drained. Santanoni soils are sandy and gravelly, moderately deep to bedrock, and somewhat excessively drained and excessively drained.

Typical pedon of Wallface loamy sand, in a map unit of Wallface-Skylight complex, 15 to 35 percent slopes, very rocky, very bouldery, in a wooded area, in the town of North Elba; about .4 miles due east of Scott Pond, at end of pass; USGS Santanoni 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 09 minutes 02 seconds N. and Long. 74 degrees 01 minutes 46 seconds W.

Oe—0 to 4 inches, dark reddish brown (5YR 2.5/2) moderately decomposed (hemic) plant material; weak fine granular structure; friable; many fine and medium, and common coarse roots; 2 percent gravels and 1 percent stones; extremely acid; gradual wavy boundary.

Oa—4 to 9 inches, black (5YR 2.5/1) highly decomposed (sapric) plant material; weak fine granular structure; friable; many fine and medium, and common coarse roots; 3 percent gravels and 1 percent stones; extremely acid, clear wavy boundary. (Combined thickness of the O horizons is 6 to 20 inches.)

E—9 to 10 inches; dark reddish gray (2.5YR 4/1) loamy sand; weak fine granular structure; friable; common fine and few medium roots; 3 percent gravels and 2 percent stones; extremely acid; clear wavy boundary. (1 to 5 inches thick)

Bhs1—10 to 18 inches; reddish black (2.5YR 2.5/1) loam; weak fine and medium granular structure; friable; common fine and few medium roots; 3 percent gravels and 2 percent stones; extremely acid; gradual wavy boundary.

Bhs2—18 to 25 inches; dark reddish brown (5YR 2.5/2) sandy loam; weak medium subangular blocky structure; friable; few fine roots; 5 percent gravels and 4 percent stones; very strongly acid; clear wavy boundary.

Bhs3—25 to 35 inches; dark reddish brown (5YR 3/2) gravelly sandy loam; weak medium subangular blocky structure; friable; 24 percent gravels and 4 percent stones; very strongly acid; clear wavy boundary (Combined thickness of the Bhs horizons is 10 to 25 inches).

BC—35 to 38 inches; brown (10YR 4/3) fine sandy loam; weak medium subangular blocky structure; friable; 10 percent gravels and 4 percent stones; very strongly acid; abrupt wavy boundary (0 to 10 inches thick).

R—38 inches; Marcy anorthosite bedrock.

The thickness of the solum ranges from 20 to 39 inches from the mineral surface. Rock fragment content ranges from 5 to 35 percent by volume throughout the soil. Stones and boulders cover from .01 to 15 percent of the surface. Reaction ranges from ultra acid to very strongly acid in the surface and subsurface horizons, and from extremely acid to strongly acid in the subsoil.

The O horizons have hue of 10R to 10YR or are neutral, with value and chroma of 3 or less. This horizon is slightly decomposed (fibric), moderately decomposed (hemic), or highly decomposed (sapric) plant material. The horizon has weak or moderate, fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The A horizon (where present), has hue of 7.5YR to 2.5Y, value of 2 to 3, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, or coarse sandy loam in the fine-earth fraction. Structure is weak or moderate, fine or medium granular. Consistence is very friable or friable.

The E horizon has hue of 2.5YR to 10YR, value of 3 to 6, and chroma of 1 or 2. Texture is fine sandy loam, sandy loam, coarse sandy loam, loamy fine sand or loamy sand in the fine-earth fraction. This horizon has weak fine or medium granular or subangular blocky structure. Consistence is very friable or friable.

The Bhs horizons and Bh horizons (where present), have hue of 10R to 7.5YR, with value and chroma of 3 or less. The Bhs and Bh horizons are loam, fine sandy loam, sandy loam, and coarse sandy loam. Ortstein is present in less than 50 percent of some horizons. The horizons have weak or moderate, fine, medium, or coarse granular or subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm. It is moderately or strongly smeary.

The Bs (where present) horizon has hue of 5YR or 7.5YR, value of 3 to 5, and chroma of 3 or 4. It is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, and some pedons have weak platy structure. Consistence is very friable to firm.

The BC horizon has hue of 10YR or 2.5Y, value of 3 to 5, and chroma of 3 to 6. Texture is fine sandy loam, sandy loam or coarse sandy loam in the fine-earth fraction. They have weak or moderate, fine, medium, or coarse subangular blocky structure, and some pedons have weak platy structure. It is friable to firm.

Bedrock is anorthositic gneiss (metamorphosed anorthosite).

Wegatchie Series

The Wegatchie series consists of very deep, poorly drained soils in level or depressional areas on lake plains and in basins on uplands. Wegatchie soils formed in silty clay sediments deposited in still water. Slopes range from 0 to 3 percent.

Wegatchie soils are associated on the landscape with Depeyster, Hailesboro, Burnt Vly, Searsport, Nicholville, Roundabout, and Monadnock soils. Depeyster soils are moderately well drained. Hailesboro soils are somewhat poorly drained. Burnt Vly soils are very poorly drained and are organic. Searsport soils are very poorly drained and sandy. Nicholville and Roundabout soils are silty and are moderately well drained and somewhat poorly drained respectively. Monadnock soils are loamy and well drained.

Typical pedon of Wegatchie silt loam, 0 to 3 percent slopes, in a meadow, St. Lawrence County, New York; town of Hammond, 40 feet west of Oak Point Road and 4,200 feet south of the junction of Oak Point Road and River Road; USGS Morristown NY topographic quadrangle; NAD 1927; lat. 44 degrees 30 minutes 00 seconds N. and long. 75 degrees 44 minutes 30 seconds W.

Ap—0 to 8 inches; very dark gray (10YR 3/1) silt loam, grayish brown (10YR 5/2) dry; weak medium and coarse subangular blocky structure parting to fine and medium granular; friable; slightly sticky; common fine and few medium roots; few fine prominent dark brown (7.5YR 3/4) masses of iron oxides; neutral; abrupt smooth boundary.

Bg1—8 to 13 inches; gray (10YR 5/1) clay loam; moderate fine and medium subangular blocky structure; friable; common fine roots; common fine tubular and vesicular pores; few macropores; few faint silt coats on faces of peds; common fine faint grayish brown (2.5Y 5/2) and light brownish gray (2.5Y 6/2) areas of iron depletions, and many fine and medium prominent brown (7.5YR 4/4) masses of iron oxides; neutral; abrupt smooth boundary.

Bg2—13 to 19 inches; dark gray (10YR 4/1) silty clay loam, gray (10YR 5/1) faces of peds; moderate very fine, fine and medium angular blocky structure; friable; few fine roots; common fine vesicular and tubular pores; few macropores; few faint silt coats on faces of peds; many fine and medium prominent brown (7.5YR 5/4) and strong brown (7.5YR 4/6) masses of iron oxides; neutral; abrupt smooth boundary.

BCg—19 to 40 inches; dark gray (10YR 4/1) silt loam, grayish brown (10YR 5/2) faces of peds; moderate coarse prismatic structure; firm; few fine roots on faces of prisms; many fine and medium tubular and vesicular pores; common fine prominent strong brown (7.5YR 5/8) and many medium prominent yellowish brown (10YR 5/6) masses of iron oxides; slightly alkaline; abrupt smooth boundary.

C—40 to 72 inches; yellowish brown (10YR 5/6) silt loam; weak medium plates breaking along depositional planes; firm; many medium distinct gray (10YR 6/1) silt loam varves; 10 percent rock fragments; slightly effervescent, slightly alkaline.

The thickness of the solum ranges from 20 to 40 inches. Bedrock is at depths greater than 60 inches. The depth to carbonates ranges from 20 to 60 inches. Rock fragments, mostly gravel, range from 0 to 2 percent by volume in the solum and from 0 to 10 percent in the C horizon. Unless the soil is limed, reaction ranges from moderately acid through neutral in the surface layer, from slightly acid to slightly alkaline in the subsoil, and from neutral to moderately alkaline in the substratum.

The Ap horizon is neutral or has hue of 10YR, value of 2 or 3, and chroma of 0 to 2. Texture of the fine-earth fraction is silt loam, very fine sandy loam, or loam.

The B horizon is neutral or has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 0 to 2. Texture of the fine-earth fraction is silt loam, silty clay loam, clay loam, or very fine sandy loam.

The BC horizon is neutral or has hue of 7.5YR to 5Y, value of 4 or 5, and chroma of 0 to 2. Texture of the fine-earth fraction is similar to the B horizon.

The C horizon has hue of 7.5YR to 5Y, value of 3 to 6, and chroma of 1 to 6; chroma of 3 to 6 is restricted to depths greater than 30 inches. Texture of the fine-earth fraction is very fine sandy loam, silt loam, clay loam, or silty clay loam and it is commonly varved.

Whallonsburg Series

The Whallonsburg series consists of very deep, very poorly drained soils in depressions on lake plains in the Champlain Valley. Whallonsburg soils formed in deep, saturated, decomposing plant material overlying clayey sediments (fig. 47). Slopes range from 0 to 2 percent.

Whallonsburg soils are associated on the landscape with Kingsbury, Covington, Livingston, Windsor, and Rippowam soils. Kingsbury soils are clayey and somewhat poorly drained. Covington soils are clayey and poorly drained. Livingston soils are clayey and very poorly drained. Windsor soils are sandy and excessively drained. Rippowam soils are loamy and poorly drained.

Typical pedon of Whallonsburg mucky peat, 0 to 2 percent slopes, in the town of Crown Point, 3,000 feet south of the intersection of Factoryville Road and Russell Street, 540 feet east of Factoryville Road, in a woodland swamp; USGS Crown Point, NY 7.5 minute topographic quadrangle; NAD 1983; lat. 43 degrees 57 minutes 30 seconds N. and long. 73 degrees 26 minutes 42 seconds W..

Oe—0 to 2 inches, dark reddish brown (5YR 3/3) hemic material; 70 percent unrubbed fiber, 30 percent rubbed fiber; weak medium granular structure; friable; many fine, common medium, and few coarse roots; slightly acid; abrupt smooth boundary.

Oa1—2 to 12 inches, black (N 2.5/0) sapric material; 40 percent unrubbed fiber, 12 percent rubbed fiber; weak medium granular structure; friable; many fine, common medium, and few coarse roots; slightly acid; clear smooth boundary.

Oa2—12 to 20 inches, black (10YR 2/1) sapric material; 30 percent unrubbed fiber, 5 percent rubbed fiber; weak fine granular structure; very friable; few fine roots; slightly acid; gradual smooth boundary.

Oa3—20 to 23 inches, dark brown (7.5YR 3/2) sapric material; 30 percent unrubbed fiber, 5 percent rubbed fiber; weak fine granular structure; very friable; slightly acid; abrupt smooth boundary.

2Cg1—23 to 30 inches, gray (5Y 5/1) silty clay loam; massive; friable; slightly sticky, slightly plastic; few medium prominent yellowish brown (10YR 5/4) masses of iron accumulation; neutral; gradual smooth boundary.

2Cg2—30 to 72 inches, gray (5Y 5/1) silty clay loam; massive; friable; slightly sticky, slightly plastic; neutral.

The depth to the clayey 2C horizon ranges from 16 to 51 inches. Reaction in the organic layers ranges from very strongly acid to neutral in 0.01M calcium chloride. The pH value is 4.5 or more (in 0.01M calcium chloride) in one or more layers of organic soil materials within the control section. Woody fragments occur throughout the profile in most pedons consisting of twigs, branches, logs or stumps, and range from 0 to 30 percent by volume in the control section. Fragments range from 3/4 inch to more than a foot in diameter.

The surface tier has hue of 5YR to 2.5Y or is neutral, value of 2 to 3, and chroma of 3 or less. It is dominantly muck (sapric material); however, some pedons have surface layers of peat (fibric material) or mucky peat (hemic material). The structure of the surface tier is weak or medium, coarse to fine granular or subangular blocky, or is massive.

The organic part of the subsurface and bottom tiers have hue of 5YR to 2.5Y or is neutral, value of 2 to 3 and chroma of 4 or less. Chroma or value or both may change from 0.5 to 2 units upon rubbing. Broken faces become darker upon brief exposure to air. The layer is dominated by sapric material with a rubbed fiber content of less than 17 percent of the organic volume. The subsurface tier has granular or blocky structure

Figure 47.—Soil profile (exhumed) of the Whallonsburg series from a hand dug hole, in the town of Crown Point, in a small hardwood swamp. Note the abrupt contact between the black and dark brown mucky layers overlying the blue-gray clayey substratum. Areas made up of these soils qualify as wetlands.

or is massive. The unrubbed, well-decomposed organic material resembles woody plant tissue.

The 2Cg horizon has hue of 5Y, 2.5Y, 10YR, 10B, or is neutral, value of 3 to 6 and chroma of 0 to 3. Texture ranges from silty clay loam to clay and averages more than 35 percent clay. Some pedons have thin strata of silt or silt loam material. It is massive or varved, and friable or firm. Reaction ranges from strongly acid to moderately alkaline. In some pedons it is slightly or strongly effervescent.

Wilmington Series

The Wilmington series consists of very deep, poorly drained soils in depressions on toeslopes and footslopes of glaciated mountains in the Adirondack Upland. Wilmington soils formed in loamy sediments underlain by compact, firm lodgment till. Slopes range from 0 to 10 percent.

Wilmington soils are associated on the landscape with Ampersand, Mundalite, Rawsonville, Hogback, and Knob Lock soils. Ampersand soils are somewhat poorly drained. Mundalite soils are well drained. Rawsonville soils are 20 to 40 inches deep to meta-igneous bedrock and well drained. Hogback soils are 10 to 20 inches deep to meta-igneous bedrock and are well drained. Knob Lock soils are organic, 1 to 20 inches deep to meta-igneous bedrock, and are well drained to excessively drained.

Typical pedon of Wilmington gravelly sandy loam, in a map unit of Ampersand-Wilmington complex, 0 to 15 percent slopes, very bouldery, in a wooded area, town of Lewis, 600 feet south of a point on Wells Hill Road near Big Slash Mountain, that is 1,150 feet east of the upper crossing of Wells Hill Road and Spruce Mill Brook; USGS Ausable Forks, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 16 minutes 48 seconds N. and long. 73 degrees 39 minutes 34 seconds W.

Oi—0 to 3 inches; dark brown (7.5YR 3/2) fibric material, dominantly sphagnum; 95 percent fiber unrubbed, 80 percent rubbed; weak fine granular structure; very friable; many fine and medium roots; very strongly acid; clear wavy boundary.

Oe—3 to 5 inches; dark brown (7.5YR 3/2) hemic material; 60 percent fiber unrubbed, 20 percent rubbed; weak fine granular structure; very friable; many fine and very fine, common medium roots; very strongly acid; clear wavy boundary.

Oa—5 to 7 inches; black (7.5YR 2.5/1) sapric material; 15 percent fiber unrubbed, 2 percent rubbed; weak fine and medium granular structure; very friable; many fine and very fine, common medium roots; 1 percent cobbles; very strongly acid; abrupt wavy boundary.

E—7 to 9 inches; brown (7.5YR 5/2) gravelly sandy loam; weak fine and medium subangular blocky structure; friable; few fine vesicular pores; few fine and medium roots; 15 percent gravel; few fine prominent yellowish red (5YR 4/6) soft masses of iron accumulation; very strongly acid; clear irregular boundary.

Bh—9 to 14 inches; very dark gray (7.5YR 3/1) and dark brown (7.5YR 3/2) sandy loam; weak medium subangular blocky structure; friable, moderately smeary; few fine tubular and vesicular pores; few fine and medium roots; 10 percent gravel; common fine prominent yellowish red (5YR 4/6) soft masses of iron accumulation and few fine and medium distinct brown (7.5YR 5/2) iron depletions; very strongly acid; clear wavy boundary.

Bhs—14 to 19 inches; dark reddish brown (5YR 3/3 & 3/2) gravelly sandy loam; weak medium subangular blocky structure; friable, moderately smeary; few fine vesicular pores; few fine roots; 20 percent gravel; common medium distinct brown (7.5YR 5/2) iron depletions; very strongly acid; clear wavy boundary.

Cdg—19 to 72 inches; grayish brown (10YR 5/2) gravelly sandy loam; massive with medium and thick plate-like divisions; firm, brittle; few fine vesicular pores; 20 percent gravel; common fine and medium prominent dark reddish brown (5YR 3/3)

and common medium and coarse distinct dark yellowish brown (10YR 4/4) soft masses of iron accumulation; strongly acid.

The thickness of the mineral solum ranges from 10 to 20 inches. Depth to bedrock is greater than 60 inches. Reaction ranges from extremely acid to moderately acid in the mineral solum, and strongly acid to slightly acid in the substratum. Rock fragments are pebbles and cobbles and typically range from 5 to 35 percent in the mineral soil, but some subhorizons do not have rock fragments. Depth to redoximorphic features is less than 10 inches. Areas of iron depletion occur in the upper part of the spodic horizon.

The O horizon is fibric, hemic, or sapric material with hue of 5YR to 10YR, value 2 to 3, and chroma 0 to 2.

Some pedons have an A horizon which is neutral or has hue of 7.5YR or 10YR, value of 2 to 3, and chroma of 0 to 2. Texture is very fine sandy loam, fine sandy loam, loam, or silt loam in the fine-earth fraction.

The E horizon is neutral or has hue of 5YR to 10YR, value of 4 to 6, and chroma of 0 to 2. Texture is fine sandy loam or sandy loam in the fine-earth fraction. This horizon is 0 to 3 inches thick.

The Bh horizon is neutral or has hue of 5YR to 10YR. This horizon typically has value of 2 or 3, and chroma of 0 through 2, but higher values and chromas are allowed. Consistence is moderately or weakly smeary.

The Bhs horizon has a hue of 5YR to 10YR, with value and chroma of approximately 3 or less.

Some pedons have a BC horizon with hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 or 2.

The B and BC horizons are silt loam, loam, sandy loam, fine sandy loam, or very fine sandy loam in the fine-earth fraction.

The Cdg horizon has hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 or 2. Texture is loam, silt loam, sandy loam, very fine sandy loam, of fine sandy loam in the fine-earth fraction. Consistence is firm or very firm. Some Cdg horizons have redoximorphic features.

The Cd horizon has hue of 10YR to 5Y, value of 4 or 5, and chroma of 1 to 4. Texture is silt loam, loam, fine sandy loam, or sandy loam in the fine-earth fraction. Consistence is firm or very firm. The lower part of the Cd horizon, below 40 inches, ranges from friable to firm. Some Cd horizons have redoximorphic features.

Windsor Series

The Windsor series consists of very deep, excessively drained soils on deltas and terraces in the Champlain Valley. Windsor soils formed in stratified, water deposited, sandy sediments. Slopes range from 0 to 45 percent (fig. 48).

Windsor soils are associated on the landscape with Deerfield, Stafford, Gougeville, Vergennes, Occum, Charlton, and Chatfield soils. Deerfield soils are moderately well drained. Stafford soils are somewhat poorly drained. Gougeville soils are poorly drained. Vergennes soils are clayey and moderately well drained. Occum and Charlton soils are loamy and well drained. Chatfield soils are loamy, well drained, and 20 to 40 inches deep to meta-igneous bedrock.

Typical pedon of Windsor loamy sand, 0 to 3 percent slopes, in the town of Lewis, 170 feet southwest of a point on Twin Valley Road that is 1,580 feet northwest of the junction of Twin Valley Road and Alden Road, in a corn field; USGS Willsboro, NY 15 minute topographic quadrangle; NAD 1927; lat. 44 degrees 15 minutes 24 seconds N. and long. 73 degrees 28 minutes 36 seconds W.

Ap—0 to 10 inches, dark brown (10YR 3/3) loamy sand; moderate fine and medium granular structure; very friable; common fine and very fine roots; 1 percent rock fragments; moderately acid; abrupt smooth boundary.

Bw1—10 to 14 inches, dark yellowish brown (10YR 4/6) loamy sand; weak medium subangular blocky structure; very friable; common fine and very fine roots; 2 percent rock fragments; slightly acid; clear smooth boundary.
Bw2—14 to 19 inches, dark yellowish brown (10YR 4/4) sand; weak fine and medium subangular blocky structure; very friable; few fine and very fine roots; 5 percent rock fragments; slightly acid; clear smooth boundary.
BC—19 to 24 inches, yellowish brown (10YR 5/4) sand; weak fine and medium subangular blocky parting to weak fine granular structure; very friable; 10 percent rock fragments; slightly acid; clear smooth boundary.
C—24 to 72 inches, yellowish brown (10YR 5/4) sand; single grain; loose; 5 percent rock fragments; slightly acid.

The thickness of the solum ranges from 10 to 36 inches. Rock fragments, dominantly fine gravel, range from 0 to 10 percent by volume in the solum and from 0 to 15 percent in the substratum. Thin strata of gravel or thin subhorizons of coarse sand or loamy coarse sand are present in some pedons. Unless the soil is limed, reaction in the solum commonly is very strongly acid to moderately acid, but the range includes slightly acid. Unless the soil is limed, reaction in the substratum commonly is very strongly acid to slightly acid but the range includes neutral.

The A horizon has hue of 7.5YR or 10YR, value of 2 or 3, and chroma of 1 to 3. Disturbed pedons have an Ap horizon up to 12 inches thick with value of 3 or 4 and chroma of 2 to 4. The A or Ap horizon is loamy fine sand or loamy sand. It has weak or moderate granular structure and is very friable, friable, or loose.

Some pedons have a thin E horizon with value of 4 to 6 and chroma of 1 or 2.

The upper part of the Bw horizon has hue of 7.5YR to 2.5Y, value of 4 to 6, and chroma of 4 to 8. The lower part of Bw horizon has hue of 7.5YR to 5Y, value of 4 to 7, and chroma of 3 to 6. The Bw horizon is loamy sand or loamy fine sand in the upper

Figure 48.—Soil profile of the Windsor series from a road cut, in the town of Essex, in a White Pine plantation. Note the coarse sandy textures in the substratum. Row crops suffer moisture stress in these soils toward the end of the growing season in most years. Drier site timber species such as White and Red Pine, and Red Oak do well on these excessively drained sands.

part and loamy fine sand, loamy sand, fine sand, or sand in the lower part. The Bw horizon has weak granular or weak subangular blocky structure, or it is massive or single grain. Consistence is very friable or loose.

Some pedons have a BC horizon similar to the lower part of the Bw horizon.

The C horizon has hue of 5YR to 5Y, value of 4 to 7, and chroma of 1 to 6. Texture is fine sand, sand, loamy fine sand, or loamy sand. The horizon is massive or single grain and consistence is very friable or loose.

Wonsqueak Series

The Wonsqueak series consists of very deep, very poorly drained soils on broad flood plains, and on toeslopes and upland depressions of glaciated hills and ridges. Wonsqueak soils formed in saturated, decomposing plant material overlying loamy sediments. Slopes range from 0 to 2 percent.

Wonsqueak soils are associated on the landscape with Bucksport, Pyrities, Kalurah, Malone, Typic Endoaquolls, Nehasne, Monadnock, Tunbridge, and Lyman soils. Bucksport soils are greater than 51 inches deep to mineral soil. Pyrities, Kalurah, and Malone soils are loamy and are well drained, moderately well drained, and somewhat poorly drained respectively. Typic Endoaquolls soils are loamy. Monadnock soils are loamy over sandy or gravelly and are well drained. Nehasne and Tunbridge soils are loamy, well drained, and are 20 to 40 inches deep to marble and meta-igneous bedrock respectively. Lyman soils are loamy, well drained, and are 10 to 20 inches deep to meta-igneous bedrock.

Typical pedon of Wonsqueak muck, 0 to 2 percent slopes, in the town of Schroon, 200 feet south of a point on Johnson Pond Road that is 2,800 feet west of the junction of Johnson Pond Road and Letsonville Road; USGS Paradox Lake, NY 7.5 minute topographic quadrangle; NAD 1927; lat. 43 degrees 54 minutes 49 seconds N. and long. 73 degrees 38 minutes 54 seconds W.

Oa1—0 to 12 inches, black (10YR 2/1) broken face and rubbed muck (sapric material); 20 percent unrubbed fiber, 3 percent rubbed fiber; weak fine granular structure; very friable; about 10 percent fine sand; few fine and medium roots; moderately acid; clear wavy boundary.

Oa2—12 to 25 inches, very dark brown (10YR 2/2) broken face, black (10YR 2/1) rubbed muck (sapric material); 35 percent unrubbed fiber, 5 percent rubbed fiber; massive; friable; about 20 percent fine sand; neutral; clear smooth boundary.

2Cg1—25 to 29 inches, gray (2.5Y 5/1) sandy loam; massive; friable; 10 percent rock fragments; slightly alkaline; clear smooth boundary.

2Cg2—29 to 72 inches, gray (5Y 5/1) silt loam; common coarse prominent light olive brown (2.5Y 5/4) and few fine prominent brown (7.5YR 4/4) soft masses of iron accumulation; massive; friable; slightly alkaline.

The thickness of the organic soil material and the depth to the mineral substratum ranges from 16 to 51 inches. The content of woody fragments in the organic material ranges from 0 to 20 percent. The content of mineral material in the organic layers ranges from 0 to 20 percent. The fibers are typically of herbaceous origin but the fibers in some layers are of woody origin. In some pedons, fibers from sphagnum moss are dominant in the surface tier and make up thin layers in the subsurface and bottom tier. The reaction of the organic material in 0.01 M calcium chloride ranges from 4.0 to 6.5, but is 4.5 or more in at least some part of the control section.

The surface tier is neutral or has hue of 2.5YR to 10YR, value of 2 to 3, and chroma of 0 to 2. The surface tier is typically sapric material but in some pedons may be hemic or fibric materials with or without sapric materials. It is massive or has weak, fine or medium, granular or subangular blocky structure. Consistence is nonsticky or slightly sticky. The surface tier ranges from extremely acid to slightly acid in 0.01 M calcium chloride.

The subsurface and bottom tiers are neutral or have hue of 2.5YR to 2.5Y, value of 2 to 4, and chroma of 0 to 2. The tiers are typically sapric material but some pedons have thin layers of fibric material with a total thickness of less than 5 inches or thin layers of hemic material with a total thickness of less than 10 inches. The subsurface and bottom tiers are massive or have platy, granular or subangular blocky structure. Consistence is nonsticky or slightly sticky. Reaction ranges from very strongly acid to slightly acid in 0.01 M calcium chloride.

The C horizon is neutral or has hue of 5YR to 5GY, value of 3 to 6, and chroma of 0 to 4. It is dominantly silt loam but ranges from sandy loam to silty clay loam in the fine-earth fraction. The upper part has mucky mineral material in some pedons. Consistence is non-sticky, slightly sticky, or moderately sticky and nonplastic to plastic. The content of rock fragments ranges from 0 to 20 percent and is mostly gravel. Reaction ranges from very strongly acid to slightly alkaline.

Formation of the Soils

The first part of this section describes the factors of soil formation and relates them to the soils in the survey area. The second part defines the processes of horizon development as they relate to soil formation in the area.

Factors of Soil Formation

Soils are the product of weathering and other physical or chemical processes that act on parent material. The properties of a soil at a given point on the earth's surface depend on a combination of several factors of soil formation: parent material, relief, climate, plant and animal life, and time. The relative influence of each of these factors differs from place to place, and each factor modifies the effect of the others. For example, the impact of climate over a given area is tempered by the nature of the relief or of the parent material. In many areas, the influence of a single factor is dominant (USDA NRCS, http://soils.usda.gov/education/facts/formation.html).

Parent Material

Parent material is the unconsolidated earthy material in which soils are formed. It influences the physical, chemical, and mineralogical composition of the soils. It also influences the rate at which soil forming processes proceed.

Most of the soils in Essex County formed in deposits left as a result of glaciation. Till is the most extensive type of parent material. Less extensive are glacial outwash, lacustrine and marine, recent alluvium, and organic deposits.

Soils formed in till have a wide range of characteristics as a result of the heterogeneous nature of these deposits, which after being transported by glacial ice, are generally a poorly sorted, random mixture of sand, silt, clay, and rock fragments ranging in size from gravel to boulders. Soils such as the Becket, Mundalite, Esther, Ampersand, and Skerry series formed in very deep tills that were deposited at the base of active, flowing glaciers and have a dense substratum. Other till soils such as the Monadnock, Fernlake, Hermon, and Sunapee series formed in material that was "dumped" out of the glaciers by mass wasting of stagnant ice, and do not have a dense layer. Although both of these deep till types have a friable and free draining surface and subsoil, downward movement of water is restricted in the first group by the dense substratum and affects how the soil develops and behaves under different uses. In many areas, the till is moderately deep or shallow over bedrock. Lyman and Tunbridge soils, for example, are shallow and moderately deep respectively to anorthositic gneiss bedrock. The fabric and rock fragments of these soils are made up mostly of the underlying anorthositic gneiss, and this affects the physical and chemical development of the soils. Farmington and Galway soils are shallow and moderately deep respectively to limestone bedrock. These soils are mostly derived from the underlying limestone bedrock which has influenced their development. Some areas have a significant amount of exposed bedrock at the surface. Rock outcrop is mapped as a major component in these areas.

As the last ice age ended, and the glacial ice melted, large quantities of meltwater transported and sorted soil and rock debris. This material is referred to as glacial

outwash and was redeposited in layers of sand and gravel on outwash plains, kame terraces, deltas, and beach ridges. Adams, Colton, and Howard are examples of soils formed in this material. Adams and Colton soils are made up of material weathered from anorthositic gneiss bedrock and are generally more acidic. Howard soils are mainly derived from limestone and are alkaline. These soils are gravelly or sandy.

At deglaciation, a huge water body formed in the Champlain Valley. Later on, an estuary replaced this fresh water body as an arm of the Atlantic Ocean, often referred to as the "Champlain Sea". Streams flowing into this pro-glacial lake (and later sea) dropped their suspended sediment over hundreds of years to form lacustrine and marine deposits. These materials range from laminated silts and very fine sands with varying amounts of clay, to mostly clay with some silt. Dunkirk, Collamer, Vergennes, and Kingsbury are examples of soils developed from this material.

In more recent times, overflowing streams have deposited alluvial material on the flood plains. Soils that formed in this material tend to have little soil development and are commonly variable in texture. Occum and Ondawa soils formed in coarser textured material and are primarily sandy loam textures. Lovewell and Cornish soils formed in finer textured deposits and are primarily silt loam textures.

Soils formed in organic deposits are mainly in closed depressions in the uplands and along the lake plain near Lake Champlain. In these very poorly drained upland depressions and marshes near the lake, dead plant material will accumulate in thick deposits over hundreds of years under saturated conditions. Pleasant Lake and Catden are examples of soils formed in well decomposed organic material.

Relief

The shape of the land surface, the slope, and the position of the land surface in relation to the water table have had a great influence on the formation of the soils in the survey area. Soils that formed in gently sloping or strongly sloping convex positions or in steeply sloping areas, where little or no runoff accumulates, commonly are well drained and do not contain any evidence of seasonal saturation, such as gray or reddish brown mottling in the soil profile. Monadnock and Charlton soils are examples. In the more gently sloping planar or concave areas, where runoff is slower, the soils generally exhibit some evidence of short periods of wetness, such as gray and reddish brown mottling (redoximorphic features) in the lower subsoil. Sunapee and Bombay soils are examples. In nearly level or slightly concave areas, the water table is typically closer to the surface for extended periods, resulting in prominent redoximorphic features close to the surface. Adirondack and Massena soils are examples. In level areas and closed depressions, the water table is at or near the surface for much of the growing season, resulting in a grayish subsoil and accumulation of organic matter in and on the surface layer. Tahawus and Sun soils are examples.

Climate

Climate, particularly temperature and precipitation, is one of the most influential of the soil forming factors. It determines to a large degree the kind of weathering processes that occur. It also affects the growth and kind of vegetation, microbial activity, and the leaching and translocation of weathered material. Most of Essex County has a humid, temperate climate which tends generally to promote the development of moderately weathered, leached soils. Soil temperature is affected by rising elevation from east to west (warmer to colder), proximity to Lake Champlain, and latitude. Precipitation follows a general east to west gradient as well going from relatively drier in the east near Lake Champlain to wetter in the west and higher elevations. Three soil temperature zones, mesic, frigid, and cryic have been

established in Essex County, and along with their respective precipitation, rates combine to greatly influence the formation of the soils. Soils in the three zones are separated based on elevation: mesic from about 95 to 500 feet in elevation, frigid from 500 to 3,000 feet, and cryic at 3,000 feet and above. Soils of the mesic zone in the Champlain Valley are warmer and moderate rates of oxidation and biological activity result in relatively moderate levels of organic matter accumulation in the surface and very little organic matter accumulation in the subsoil. Soils of the frigid zone, which makes up most of the county, are cooler and slower rates of oxidation and biological activity result in increased organic matter accumulation in the surface and in the subsoil. Soils of the cryic zone in the High Peaks Region are cold most of the year. They have relatively slow oxidation and biological activity rates and organic matter can accumulate on the surface to form thick layers, and also accumulate in the subsoil at very high levels.

More specific data is in the climate section under “General Nature of the County”.

Plant and Animal Life

Organic matter accumulation, biochemical weathering, profile mixing, nutrient cycling, and aggregate stability are all enhanced by the activities of organisms in the soil (Brady and Weil, 1999). Vegetative cover reduces soil erosion. Organic acids produced by biological activity on plant leaf and needle material bring iron and aluminum into solution by complexation and accelerate the leaching of these metals and their accumulation in the subsoil.

Earthworms and burrowing animals help to keep the soil porous and more permeable to air and water. Their waste products provide nutrients for plant uptake and cause the aggregation of soil particles and improve soil structure. Bacteria and fungi decompose vegetation which results in the release of nutrients available for plant uptake, and by-products from this decomposition also enhance soil structure and health.

The original vegetation in the survey area was native forest consisting of northern hardwoods and conifers. The loss of nutrients through leaching is slow under hardwoods because the trees take up large quantities of nutrients and return much of them to the surface each year as leaf litter. Conifers, such as spruce, fir, and pines, do not use large amounts of nutrients; therefore, leaching is more rapid under them than it is under hardwoods. Soils generally tend to be more acid under conifers than hardwoods.

In many of the soils on uplands which have dense substratums or are moderately deep or shallow to bedrock, the rooting depth is shallow and the trees are susceptible to windthrow. As a result, the soil materials are being mixed gradually over time.

Human activity, such as the clearing of trees and the cultivating of land, also has influenced formation of the soils. Nutrients that have been added as fertilizer are applied, plowing has mixed and destroyed some soil horizons, and erosion has been accelerated in many areas.

Time

Time is a passive, but important, soil-forming factor. In geological terms, the deposits in which soils formed in Essex County are relatively young. They were deposited when the last glacier receded about 10,000 to 15,000 years ago.

The degree of profile development reflects the age of a soil and the influence of other soil-forming factors. The soils in the survey area have not all reached the same stage of profile development because of the influence of the other soil-forming factors. Because the time factor is relatively constant within the county (except for deposits on

flood plains), the difference in appearance of the soils and the depth of weathering is commonly a function of differences in climate and parent material.

An immature soil is one that has not had enough time to develop distinct horizons. The soils in the Fluvaquents-Udifluvents map unit are an example of immature soils that lack distinct horizonation. They formed in recent alluvium in areas that are regularly flooded and receive periodic sediment deposition. The deposition regularly interrupts the time for soil development, resulting in thin horizons or irregular soil profiles.

Processes of Soil Formation

The soil-forming processes result in the development of distinct layers, or soil horizons. These horizons can be viewed in a vertical cut of soil, known as a soil profile. The soil profile extends from the surface downward into material that is little altered by the soil-forming processes. Most soils contain three major horizons, called A, B, and C horizons (surface, subsoil, and substratum). Many soils in Essex County also have O and E horizons (surface and subsurface).

Many processes are involved in the formation of soil horizons. Some of these processes include the accumulation of organic material, the leaching of soluble salts and minerals, translocation of iron and aluminum by organic acids, the translocation of clay minerals, and the reduction and transfer of iron under saturated conditions (Brady and Weil, 1999).

With very few exceptions, the soils of Essex County classify within five broad Soil Orders: Spodosols, Inceptisols, Alfisols, Entisols, and Histosols.

Most of the soils of the county classify as Spodosols (about 81 percent) and are found throughout the frigid and cryic temperature zones. The name is derived from the Greek word “spodos” meaning “wood ash”. They are characterized by the formation of a spodic subsoil horizon which has distinct morphology of a reddish brown or dark reddish brown subsoil (Bs or Bhs horizon), underlying an ashy colored (light gray) subsurface horizon (E horizon). The ashy colored E horizon generally underlies a “duff” or organic surface horizon (O horizon) made up of slightly to highly decomposed needle, leaf, and twig material. The E horizon is often mistaken for a burned surface layer presumably from an old forest fire, but in reality, the E horizon is formed when soil materials are leached from it and redeposited into the Bs or Bhs horizon(s) (spodic horizon) immediately below. Spodosols for the most part form in cool, humid climates in the mid to high latitudes of the world. Most Spodosols in the county form in coarse textured parent materials that are of glacial outwash or till origin. Textures are generally fine sandy loam, sandy loam, loamy sand, or sand. These parent materials are derived primarily from metamorphosed igneous intrusive bedrock, are very resistant to weathering, and tend to be acidic. Spodic horizon expression is generally strongest under coniferous forest canopy which tends to promote a more acidic soil environment; however, spodic horizon development readily occurs under mixed hardwood vegetation in the more acidic parent materials. Prevailing theory of Spodosol formation suggests that at first most base cations, especially calcium, are leached out of the upper part of the mineral soil column. Organic or “duff” layers build up on the surface from reduced microbial activity and slower decomposition rates, due to cooler temperatures and acidic conditions. As rainwater percolates through the O horizon, humic acids are leached down into the top of the soil and begin to break down minerals releasing iron, aluminum, and other elements. Iron and aluminum build complexes with these organic acids, become water soluble, and are leached (elluviate) out of the top mineral layers and precipitate (illuviate) into the B horizon as complexes of organic matter and iron and aluminum oxides. Continued removal of iron, aluminum, and other elements by these organic complexing agents results in the weathered E horizon, which is rich in quartz and other resistant minerals (Grunwald, 2008). The

quartz and other resistant minerals give the E horizon its ashy appearance. The precipitated iron, and variable concentrations of organic matter, give the B horizon its reddish brown or dark reddish brown appearance. Within Essex County, as one travels higher in elevation, colder in climate, and higher in rainfall, the spodic horizon becomes thicker and higher in organic matter content. Cold temperatures in the High Peaks Region, and reduced microbial activity probably contribute to the often very thick (greater than 8 inch) O horizons that form. Higher rainfall leaches higher concentrations of these humic acids into the spodic B horizon resulting in ultra acidic conditions and very high organic matter accumulation in these mineral subsoil layers. Spodosols are generally nutrient poor and therefore make marginal at best agricultural soils. However, the pH dependent potential nutrient holding and exchange capacity of these soils is high. The water holding capacity, despite the sandy textures, is also high within the spodic horizon, due to the high organic matter and iron and aluminum oxide content. Protection of the spodic horizon from erosion is important for forest health and watershed protection. In the Lake Placid area, certified rust free seed potatoes thrive in the acidic conditions of Spodosols because the growth of pathogens is inhibited by the low pH of these soils. Becket, Monadnock, Tunbridge, Lyman, Skerry, and Adirondack soils are Spodosols commonly found in the county.

Inceptisols are the next most common (about 7 percent) of the soil “Orders” found in Essex County. The name of this Order is derived from the Latin word “incepum” meaning “beginning”. They are characterized by the formation of a cambic subsoil horizon which typically shows relatively weak development including weathering of soil particles, release and oxidation of iron that imparts bright brown colors on well drained landforms, and weak formation of soil structure. The topsoil or A horizon, which has relatively low organic matter accumulation, generally forms above the cambic B horizon. On poorly drained landforms, where the water table is at or near the surface for much of the growing season, the cambic subsoil horizon forms when iron is reduced under saturated conditions imparting gray colors. Inceptisols in Essex County typically have a simple A, B, C sequence of horizon formation, and for the most part have developed in coarse textured parent materials of till origin which are fine sandy loams or sandy loams. Inceptisols are found all over the world and generally form on relatively “young” landscapes where the processes of soil formation have not had much time, in geologic terms, to act on the soil. They can form in a wide range of climatic conditions except arid regions. The cambic horizon often shows weak indication of either an argillic or spodic horizon, but not enough to qualify as either. It may be conceptually regarded as a signature of early stages of soil development, i.e soil structure or color development (Grunwald, 2008). Most of the Inceptisols mapped in Essex County are found in the mesic soil temperature zone adjacent to Lake Champlain; however, there are some Inceptisols mapped in the eastern foothills part of the frigid zone just west of the Champlain Valley. Many of these colder Inceptisols have developed in parent materials that have high amounts of limestone or marble bedrock material, and the reason spodic horizons have not developed in these soils may be because they still have high levels of calcium and base cations that have not yet leached out of the soil. Pyrities, Nehasne, Kalurah, and Malone are examples of frigid Inceptisols. Inceptisols in the warmer (mesic) Champlain Valley part of the county have formed in both limestone and acid gneiss parent materials. The reason that Spodosols have not developed in these warmer, acidic parent materials, may be that because of the warmer soil temperatures, microbial activity and oxidation of organic matter is greater, and the humic acids needed to form a spodic horizon are not abundant enough. Nutrient availability in these Inceptisols is parent material dependant. Because of the relatively low degree of weathering, horizons with high potential nutrient holding and exchange capacity such as an argillic horizon (discussed below), have not had time to develop. The Inceptisols formed in acidic parent materials are generally nutrient poor, existing nutrients are easily leached out, and they rank as

marginal agricultural soils. Basic (limestone) parent material Inceptisols are inherently very high in nutrients, so even with comparable rates of leaching there is still enough available nutrients to rank these as relatively good agricultural soils. Charlton, Chatfield, and Hollis are examples of mesic Inceptisols formed in acidic parent materials. Nellis, Amenia, Farmington, Galway, Pittsfield, Georgia, and Massena are examples of mesic Inceptisols formed in limestone (basic) parent materials.

Alfisols is an important soil “Order” found in Essex County despite its small extent (about 3 percent). The origin of the name of this Order is derived from the word pedalfer, which is an obsolete term used under the old US Soil Classification System. They are characterized by the formation of an *argillic* subsoil horizon in which fine clay particles are translocated (elluviated) from an overlying A and/or E horizon and precipitate (illuviate) into the underlying B (argillic) horizon. In well developed argillic horizons, fine clay particles that appear as patchy or continuous glossy films on the surfaces of structural aggregates, can be seen with the help of a hand lens. Typically, an A horizon with relatively low organic matter content, and an E horizon that appears lighter in color than both A and B horizons are common in Alfisols. By definition, the argillic horizon must have at least 20 percent more clay than the overlying horizon (either A or E), so texturally the argillic feels more sticky when rubbed than its overlying horizons. Alfisols on well drained landforms also exhibit weathering of soil particles, and release and oxidation of iron that will display bright brown colors. Structural development of soil aggregates is also generally well expressed. In Essex County, these soils have almost exclusively formed in the silty clay or clayey lacustrine (lake laid) or marine parent materials discussed above. These parent materials are already moderately high to very high in clay and are high in bases, especially calcium. Alfisols can be found all over the world usually in warm temperate climates with a wide range of rainfall rates. They typically form on much older landscapes than are found in Essex County. Alfisols formation in this county is probably based on several factors. Weathering of primary minerals by water in the surface mineral soil layers will form fine silicate clays of high base status. Free calcium carbonate, which is abundant in the parent material, must be leached further down in the soil profile because it tends to flocculate the clay into large particles and prevent downward movement. With calcium carbonate removed, fine clay can disperse in aqueous suspension, and translocation from the A and E horizons into the Bt (argillic) horizon can occur (with or without the aid of complexing organic compounds) under the influence of percolation water. The process of clay translocation is also called lessivage. An erratic moisture regime favors the formation of an argillic horizon, because the processes of weathering and translocation are supported by percolation water and the precipitation of the translocated material by dry moisture conditions (Grunwald, 2008). Perhaps one of the reasons alfisols can form on these particular landscapes of Essex County is that the parent materials were already sorted and redeposited as fine grained particles, so it does not take as long to weather them into fine clay particles. Almost all of the Alfisols in the county can be found in the mesic zone in the Champlain Valley, however there are a few isolated lacustrine (lake laid) terraces in the Ausable River valley part of the frigid zone where these soils have formed. They are inherently nutrient rich, the argillic horizon has high nutrient holding and exchange capacity, and they are among the best agricultural soils found in the county. Vergennes, Kingsbury, Covington, Dunkirk, Collamer, Niagara, Depeyster, and Hailesboro are examples of Alfisols found in the county.

Entisols is another important soil “Order” found in Essex County despite its small extent (about 3 percent). The origin of the name of this Order is derived from the word recent, implying very young or recently deposited. These soils have almost exclusively developed in sandy, deltaic, glacial outwash deposits of the mesic and frigid zones that lack a spodic horizon, and in poorly drained flood plain deposits. They are characterized by the formation of a very weakly developed *cambic* subsoil horizon in

better drained sandy deposits, and the lack of any subsoil horizon in poorly drained recent alluvial deposits. The cambic horizons show some limited weathering of soil particles, and subsequent release and oxidation of iron imparting bright brown colors. They are usually single grain or structureless due to their sandy textures. An A horizon, which has very low organic matter accumulation, generally forms above the cambic B horizon. Entisols in Essex County typically have a simple A, B, C sequence of horizon formation, but on poorly drained landforms, they have just an A, C profile. Entisols can be found all over the world and are typical of very young landscapes such as flood plains, or are common in environments where soil formation is retarded by lack of weathering agents (lack of water in deserts), or continuous saturation. Entisols formation on poorly drained flood plains is due to the young age of the parent material and prolonged saturation. Sandy deltaic deposits in the mesic soil areas of the Champlain Valley are probably transitional to Spodosols, but because they are warmer and have higher oxidation rates of organic matter, spodic horizon formation is retarded. The limited sandy Entisols found in the frigid soil areas, seem to have a higher base saturation, and given enough time for the bases to leach out, spodic horizons will form in these soils as well. Entisols are generally marginal agricultural soils because of there sandy textures, low water holding capacity, and droughtiness. Some of these soils have higher base status and are a little better for agriculture, but droughtiness and rapid leaching are still a problem. Poorly drained flood plain soils are saturated for prolonged periods and make poor agricultural soils. Windsor, Deerfield, Stafford, Gougeville, Champlain, Mooers, Rippowam, and Rumney are examples of Entisols found in the county.

Histosols is the last important soil "Order" found in Essex County that will be discussed and actually makes up about 6 percent of the county. The name is derived from the Greek word "histos" meaning "tissue". They are characterized by the accumulation of very thin (at least an inch) to very thick (greater than 51 inch) layers of decomposed organic matter from dead plant remains. Two major "Suborders" of Hisotols are found in Essex County. The first "Suborder" that will be discussed is the more familiar of the two and is named *Saprists*. Saprists are found in the wetlands (bogs, swamps, and marshes) of the county and form under saturated anaerobic conditions. They are scattered throughout the mesic and frigid soil temperature zones of the county. As the wetland plants die, the residues of these plants sink into the water, which inhibits their oxidation by reducing oxygen availability, and consequently acts as a partial preservative (Brady and Weil, 1999). The lack of oxygen, under saturated anaerobic conditions, reduces microbial activity and retards the oxidation of organic matter. Saprists must have accumulated organic layers that are at least 16 inches thick. Most of that thickness must be highly decomposed plant material. In Essex County some Saprists have developed in a nutrient rich (euic) basic environment, and the remainder have developed in an acid (dysic) environment. Saprists make up only about 2 percent of the soils in the county. The second, and less well known, "Suborder" of Histosols found in the county is the *Folists*. Folists are also made up of decomposed organic matter, but develop in cool, aerobic, non-saturated environments. They are only found in the frigid and cryic soil temperature zones of the county. Because of the colder climatic conditions at higher elevations, microbial activity and oxidation rates of organic matter are reduced and thick organic layers are able to build up on the surfaces of otherwise well drained landforms. In Essex County, Folists only form over acid gneiss bedrock and can range from 1 to 20 inches in thickness. They can have up to 4 inches of mineral soil between the organic layers and the bedrock, but the organic layers must be two thirds or more of the thickness of the whole horizon. Folists are common on very steep landforms of the High Peaks Region and some of the lower foothills where there are many exposed ledges, and make up about 4 percent of the county. These soils are very acidic, and the acidity seems to increase with elevation. Saprists are found in wetlands and are the basis of life in these

important habitats. Wetlands provide fish and wildlife habitat, natural water quality improvement, flood storage, shoreline erosion protection, and substantial biodiversity (US EPA, 2009). Folists provide important habitat for plants and animals in an otherwise barren (bare rock) environment. Because of the very high moisture holding capacity of the organic matter, Folists are an important component facilitating watershed protection. Bucksport, Burnt Vly, Catden, Pleasant Lake, Whallonsburg and Wonsqueak are examples of Saprists found in the county. Knob Lock and Ricker are examples of Folists found in the county.

Soil morphological features known as *redoximorphic* features, are formed by the processes of reduction, translocation, and oxidation of iron and manganese oxides in seasonally saturated soils (Vepraskas, 1992). They can be found in any of the wetter members of the soil orders discussed above (except in Saprists which are already continually saturated), and their presence will generally indicate the depth of seasonal saturation within the soil profile. In saturated horizons, iron and manganese are reduced by bacteria decomposing organic matter under anaerobic conditions. The reduced iron and manganese oxide minerals dissolve in water leaving gray colors (depletions), and diffuse onto other parts of the soil horizon or may be leached out completely. Iron and manganese oxides will translocate to other parts of the horizon and precipitate as bright red, orange, or black concentrations when they encounter oxygen from live roots, or soils aerate from fluctuating water table depth due to transpiration and percolation. In soils that are almost continually saturated, gray soil matrix colors form (gleying) simply by the reduction of iron in the presence of soluble organic matter and microorganisms. In moderately well drained and somewhat poorly drained soils, such as the Skerry and Adirondack series, reddish brown redox-concentrations and gray redox-depletions indicate the translocation of iron compounds, and the relative depths of seasonal high water tables. In the very poorly drained Tahawus soils, gray matrix colors of the subsoil and substratum indicate the continual reduction of iron minerals.

Glossary

Ablation till. Loose, permeable till deposited during the final downwasting of glacial ice. Lenses of crudely sorted sand and gravel are common.

Aeration, soil. The exchange of air in soil with air from the atmosphere. The air in a well aerated soil is similar to that in the atmosphere; the air in a poorly aerated soil is considerably higher in carbon dioxide and lower in oxygen.

Aggregate, soil. Many fine particles held in a single mass or cluster. Natural soil aggregates, such as granules, blocks, or prisms, are called peds. Clods are aggregates produced by tillage or logging.

Alluvial fan. The fanlike deposit of a stream where it issues from a gorge upon a plain or of a tributary stream near or at its junction with its main stream.

Alluvium. Material, such as sand, silt, or clay, deposited on land by streams.

Animal unit month (AUM). The amount of forage required by one mature cow of approximately 1,000 pounds weight, with or without a calf, for 1 month.

Aquic conditions. Current soil wetness characterized by saturation, reduction, and redoximorphic features.

Aqueous. Of, relating to, or resembling water; made from, with, or by water (an aqueous solution).

Argillic horizon. A subsoil horizon characterized by an accumulation of illuvial clay.

Aspect. The direction in which a slope faces.

Available water capacity (available moisture capacity). The capacity of soils to hold water available for use by most plants. It is commonly defined as the difference between the amount of soil water at field moisture capacity and the amount at wilting point. It is commonly expressed as inches of water per inch of soil. The capacity, in inches, in a 40-inch profile or to a limiting layer is expressed as:

Very low	0 to 2.4
Low	2.4 to 3.2
Moderate	3.2 to 5.2
High	more than 5.2

Backslope. The position that forms the steepest and generally linear, middle portion of a hillslope. In profile, backslopes are commonly bounded by a convex shoulder above and a concave footslope below.

Basal area. The area of a cross section of a tree, generally referring to the section at breast height and measured outside the bark. It is a measure of stand density, commonly expressed in square feet.

Base saturation. The degree to which material having cation-exchange properties is saturated with exchangeable bases (sum of Ca, Mg, Na, and K), expressed as a percentage of the total cation-exchange capacity.

Bedding planes. Fine strata, less than 5 millimeters thick, in unconsolidated alluvial, eolian, lacustrine, or marine sediment.

Bedding system. A drainage system made by plowing, grading, or otherwise shaping the surface of a flat field. It consists of a series of low ridges separated by shallow, parallel dead furrows.

Bedrock. The solid rock that underlies the soil and other unconsolidated material or that is exposed at the surface.

Bedrock-controlled topography. A landscape where the configuration and relief of the landforms are determined or strongly influenced by the underlying bedrock.

Bottom land. The normal flood plain of a stream, subject to flooding.

Boulders. Rock fragments larger than 2 feet (60 centimeters) in diameter.

Breast height. An average height of 4.5 feet above the ground surface; the point on a tree where diameter measurements are ordinarily taken.

Broadly defined map unit. Map unit boundaries were plotted and verified at wide intervals. Maps were made at a scale of 1:62.500 or 5,208 feet to the inch, and the allowable minimum size of a soil delineation is 40 acres (Order 3 soil survey).

Brush management. Use of mechanical, chemical, or biological methods to make conditions favorable for reseeding or to reduce or eliminate competition from woody vegetation and thus allow understory grasses and forbs to recover. Brush management increases forage production and thus reduces the hazard of erosion. It can improve the habitat for some species of wildlife.

Calcareous soil. A soil containing enough calcium carbonate (commonly combined with magnesium carbonate) to effervesce visibly when treated with cold, dilute hydrochloric acid.

Canopy. The leafy crown of trees or shrubs. (See Crown.)

Capillary water. Water held as a film around soil particles and in tiny spaces between particles. Surface tension is the adhesive force that holds capillary water in the soil.

Catena. A sequence, or “chain,” of soils on a landscape that formed in similar kinds of parent material but have different characteristics as a result of differences in relief and drainage.

Cation. An ion carrying a positive charge of electricity. The common soil cations are calcium, potassium, magnesium, sodium, and hydrogen.

Cation-exchange capacity. The total amount of exchangeable cations that can be held by the soil, expressed in terms of milliequivalents per 100 grams of soil at neutrality (pH 7.0) or at some other stated pH value. The term, as applied to soils, is synonymous with base-exchange capacity but is more precise in meaning.

Chiseling. Tillage with an implement having one or more soil-penetrating points that shatter or loosen hard, compacted layers to a depth below normal plow depth.

Cirque. A semicircular, concave, bowllike area that has steep faces primarily resulting from glacial ice and snow abrasion.

Clay. As a soil separate, the mineral soil particles less than 0.002 millimeter in diameter. As a soil textural class, soil material that is 40 percent or more clay, less than 45 percent sand, and less than 40 percent silt.

Clay depletions. Low-chroma zones having a low content of iron, manganese, and clay because of the chemical reduction of iron and manganese and the removal of iron, manganese, and clay. A type of redoximorphic depletion.

Clay film. A thin coating of oriented clay on the surface of a soil aggregate or lining pores or root channels. Synonyms: clay coating, clay skin.

Climax plant community. The stabilized plant community on a particular site. The plant cover reproduces itself and does not change so long as the environment remains the same.

Coarse textured soil. Sand or loamy sand.

Cobble (or cobblestone). A rounded or partly rounded fragment of rock 3 to 10 inches (7.6 to 25 centimeters) in diameter.

Cobbly soil material. Material that has 15 to 35 percent, by volume, rounded or partially rounded rock fragments 3 to 10 inches (7.6 to 25 centimeters) in diameter. Very cobbly soil material has 35 to 60 percent of these rock fragments, and extremely cobbly soil material has more than 60 percent.

COLE (coefficient of linear extensibility). See Linear extensibility.

Colluvium. Soil material or rock fragments, or both, moved by creep, slide, or local wash and deposited at the base of steep slopes.

Complex slope. Irregular or variable slope. Planning or establishing terraces, diversions, and other water-control structures on a complex slope is difficult.

Complex, soil. A map unit of two or more kinds of soil or miscellaneous areas in such an intricate pattern or so small in area that it is not practical to map them separately at the selected scale of mapping. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas.

Concretions. Cemented bodies with crude internal symmetry organized around a point, a line, or a plane. They typically take the form of concentric layers visible to the naked eye. Calcium carbonate, iron oxide, and manganese oxide are common compounds making up concretions. If formed in place, concretions of iron oxide or manganese oxide are generally considered a type of redoximorphic concentration.

Conservation cropping system. Growing crops in combination with needed cultural and management practices. In a good conservation cropping system, the soil-improving crops and practices more than offset the effects of the soil-depleting crops and practices. Cropping systems are needed on all tilled soils. Soil-improving practices in a conservation cropping system include the use of rotations that contain grasses and legumes and the return of crop residue to the soil. Other practices include the use of green manure crops of grasses and legumes, proper tillage, adequate fertilization, and weed and pest control.

Conservation tillage. A tillage system that does not invert the soil and that leaves a protective amount of crop residue on the surface throughout the year.

Consistence, soil. Refers to the degree of cohesion and adhesion of soil material and its resistance to deformation when ruptured. Consistence includes resistance of soil material to rupture and to penetration; plasticity, toughness, and stickiness of puddled soil material; and the manner in which the soil material behaves when subject to compression. Terms describing consistence are defined in the "Soil Survey Manual."

Contour stripcropping. Growing crops in strips that follow the contour. Strips of grass or close-growing crops are alternated with strips of clean-tilled crops or summer fallow.

Control section. The part of the soil on which classification is based. The thickness varies among different kinds of soil, but for many it is that part of the soil profile between depths of 10 inches and 40 or 80 inches.

Corrosion. Soil-induced electrochemical or chemical action that dissolves or weakens concrete or uncoated steel.

Cover crop. A close-growing crop grown primarily to improve and protect the soil between periods of regular crop production, or a crop grown between trees and vines in orchards and vineyards.

Cropping system. Growing crops according to a planned system of rotation and management practices.

Crop residue management. Returning crop residue to the soil, which helps to maintain soil structure, organic matter content, and fertility and helps to control erosion.

Crown. The upper part of a tree or shrub, including the living branches and their foliage.

Culmination of the mean annual increment (CMAI). The average annual increase per acre in the volume of a stand. Computed by dividing the total volume of the stand by its age. As the stand increases in age, the mean annual increment continues to increase until mortality begins to reduce the rate of increase. The point where the stand reaches its maximum annual rate of growth is called the culmination of the mean annual increment.

Cutbanks cave (in tables). The walls of excavations tend to cave in or slough.

Deferred grazing. Postponing grazing or resting grazing land for a prescribed period.

Delta. A body of alluvium having a surface that is nearly flat and fan shaped; deposited at or near the mouth of a river or stream where it enters a body of relatively quiet water, generally a sea or lake.

Dense layer (in tables). A very firm, massive layer that has an average bulk density of more than 1.8 grams per cubic centimeter. Such a layer affects the ease of digging and can affect filling and compacting.

Depth, soil. Generally, the thickness of the soil over bedrock. Very deep soils are more than 60 inches deep over bedrock; deep soils, 40 to 60 inches; moderately deep, 20 to 40 inches; shallow, 10 to 20 inches; and very shallow, less than 10 inches.

Diversion (or diversion terrace). A ridge of earth, generally a terrace, built to protect downslope areas by diverting runoff from its natural course.

Drainage class (natural). Refers to the frequency and duration of wet periods under conditions similar to those under which the soil formed. Alterations of the water regime by human activities, either through drainage or irrigation, are not a consideration unless they have significantly changed the morphology of the soil. Seven classes of natural soil drainage are recognized—*excessively drained, somewhat excessively drained, well drained, moderately well drained, somewhat poorly drained, poorly drained,* and *very poorly drained*. These classes are defined in the "Soil Survey Manual."

Drainage, surface. Runoff, or surface flow of water, from an area.

Drumlin. A low, smooth, elongated oval hill, mound, or ridge of compact glacial till. The longer axis is parallel to the path of the glacier and commonly has a blunt nose pointing in the direction from which the ice approached.

Duff. A generally firm organic layer on the surface of mineral soils. It consists of fallen plant material that is in the process of decomposition and includes everything from the litter on the surface to underlying pure humus.

Ecological site. An area where climate, soil, and relief are sufficiently uniform to produce a distinct natural plant community. An ecological site is the product of all the environmental factors responsible for its development. It is typified by an association of species that differ from those on other ecological sites in kind and/or proportion of species or in total production.

Eluviation. The movement of material in true solution or colloidal suspension from one place to another within the soil. Soil horizons that have lost material through eluviation are eluvial; those that have received material are illuvial.

Endosaturation. A type of saturation of the soil in which all horizons between the upper boundary of saturation and a depth of 2 meters are saturated.

Eolian soil material. Earthy parent material accumulated through wind action; commonly refers to sandy material in dunes or to loess in blankets on the surface.

Ephemeral stream. A stream, or reach of a stream, that flows only in direct response to precipitation. It receives no long-continued supply from melting snow or other source, and its channel is above the water table at all times.

Episaturation. A type of saturation indicating a perched water table in a soil in which saturated layers are underlain by one or more unsaturated layers within 2 meters of the surface.

Erosion. The wearing away of the land surface by water, wind, ice, or other geologic agents and by such processes as gravitational creep.

Erosion (geologic). Erosion caused by geologic processes acting over long geologic periods and resulting in the wearing away of mountains and the building up of such landscape features as flood plains and coastal plains. Synonym: natural erosion.

Erosion (accelerated). Erosion much more rapid than geologic erosion, mainly as a result of human or animal activities or of a catastrophe in nature, such as a fire, that exposes the surface.

Escarpment. A relatively continuous and steep slope or cliff breaking the general continuity of more gently sloping land surfaces and resulting from erosion or faulting. Synonym: scarp.

Esker. A narrow, winding ridge of stratified gravelly and sandy drift deposited by a stream flowing in a tunnel beneath a glacier.

Extrusive rock. Igneous rock derived from deep-seated molten matter (magma) emplaced on the earth's surface.

Fertility, soil. The quality that enables a soil to provide plant nutrients, in adequate amounts and in proper balance, for the growth of specified plants when light, moisture, temperature, tilth, and other growth factors are favorable.

Fibric soil material (peat). The least decomposed of all organic soil material. Peat contains a large amount of well preserved fiber that is readily identifiable according to botanical origin. Peat has the lowest bulk density and the highest water content at saturation of all organic soil material.

Field moisture capacity. The moisture content of a soil, expressed as a percentage of the ovendry weight, after the gravitational, or free, water has drained away; the field moisture content 2 or 3 days after a soaking rain; also called *normal field capacity, normal moisture capacity,* or *capillary capacity*.

Fill slope. A sloping surface consisting of excavated soil material from a road cut. It commonly is on the downhill side of the road.

Fine textured soil. Sandy clay, silty clay, or clay.

Flagstone. A thin fragment of sandstone, limestone, slate, shale, or (rarely) schist 6 to 15 inches (15 to 38 centimeters) long.

Flood plain. A nearly level alluvial plain that borders a stream and is subject to flooding unless protected artificially.

Fluvial. Of or pertaining to rivers; produced by river action, as a fluvial plain.

Foothill. A steeply sloping upland that has relief of as much as 1,000 feet (300 meters) and fringes a mountain range or high-plateau escarpment.

Footslope. The position that forms the inner, gently inclined surface at the base of a hillslope. In profile, footslopes are commonly concave. A footslope is a transition zone between upslope sites of erosion and transport (shoulders and backslopes) and downslope sites of deposition (toeslopes).

Forb. Any herbaceous plant not a grass or a sedge.

Forest cover. All trees and other woody plants (underbrush) covering the ground in a forest.

Forest type. A stand of trees similar in composition and development because of given physical and biological factors by which it may be differentiated from other stands.

Fragipan. A loamy, brittle subsurface horizon low in porosity and content of organic matter and low or moderate in clay but high in silt or very fine sand. A fragipan appears cemented and restricts roots. When dry, it is hard or very hard and has a higher bulk density than the horizon or horizons above. When moist, it tends to rupture suddenly under pressure rather than to deform slowly.

Genesis, soil. The mode of origin of the soil. Refers especially to the processes or soil-forming factors responsible for the formation of the solum, or true soil, from the unconsolidated parent material.

Glacial drift. Pulverized and other rock material transported by glacial ice and then deposited. Also, the sorted and unsorted material deposited by streams flowing from glaciers.

Glacial outwash. Gravel, sand, and silt, commonly stratified, deposited by glacial meltwater.

Glacial till. Unsorted, nonstratified glacial drift consisting of clay, silt, sand, and boulders transported and deposited by glacial ice.

Glaciofluvial deposits. Material moved by glaciers and subsequently sorted and deposited by streams flowing from the melting ice. The deposits are stratified and occur as kames, eskers, deltas, and outwash plains.

Glaciolacustrine deposits. Material ranging from fine clay to sand derived from glaciers and deposited in glacial lakes mainly by glacial meltwater. Many deposits are interbedded or laminated.

Gleyed soil. Soil that formed under poor drainage, resulting in the reduction of iron and other elements in the profile and in gray colors.

Grassed waterway. A natural or constructed waterway, typically broad and shallow, seeded to grass as protection against erosion. Conducts surface water away from cropland.

Gravel. Rounded or angular fragments of rock as much as 3 inches (2 millimeters to 7.6 centimeters) in diameter. An individual piece is a pebble.

Gravelly soil material. Material that has 15 to 35 percent, by volume, rounded or angular rock fragments, not prominently flattened, as much as 3 inches (7.6 centimeters) in diameter.

Green manure crop (agronomy). A soil-improving crop grown to be plowed under in an early stage of maturity or soon after maturity.

Ground water. Water filling all the unblocked pores of the material below the water table.

Gully. A miniature valley with steep sides cut by running water and through which water ordinarily runs only after rainfall. The distinction between a gully and a rill is one of depth. A gully generally is an obstacle to farm machinery and is too deep to be obliterated by ordinary tillage; a rill is of lesser depth and can be smoothed over by ordinary tillage.

Hard bedrock. Bedrock that cannot be excavated except by blasting or by the use of special equipment that is not commonly used in construction.

Hardpan. A hardened or cemented soil horizon, or layer. The soil material is sandy, loamy, or clayey and is cemented by iron oxide, silica, calcium carbonate, or other substance.

Hard to reclaim (in tables). Reclamation is difficult after the removal of soil for construction and other uses. Revegetation and erosion control are extremely difficult.

Head out. To form a flower head.

Head slope. A geomorphic component of hills consisting of a laterally concave area of a hillside, especially at the head of a drainageway. The overland waterflow is converging.

Hemic soil material (mucky peat). Organic soil material intermediate in degree of decomposition between the less decomposed fibric material and the more decomposed sapric material.

High-residue crops. Such crops as small grain and corn used for grain. If properly managed, residue from these crops can be used to control erosion until the next crop in the rotation is established. These crops return large amounts of organic matter to the soil.

Hill. A natural elevation of the land surface, rising as much as 1,000 feet above surrounding lowlands, commonly of limited summit area and having a well defined outline; hillsides generally have slopes of more than 15 percent. The distinction between a hill and a mountain is arbitrary and is dependent on local usage.

Horizon, soil. A layer of soil, approximately parallel to the surface, having distinct characteristics produced by soil-forming processes. In the identification of soil horizons, an uppercase letter represents the major horizons. Numbers or lowercase letters that follow represent subdivisions of the major horizons. An explanation of the subdivisions is given in the “Soil Survey Manual.” The major horizons of mineral soil are as follows:

O horizon.—An organic layer of fresh and decaying plant residue.

A horizon.—The mineral horizon at or near the surface in which an accumulation of humified organic matter is mixed with the mineral material. Also, a plowed surface horizon, most of which was originally part of a B horizon.

E horizon.—The mineral horizon in which the main feature is loss of silicate clay, iron, aluminum, or some combination of these.

B horizon.—The mineral horizon below an A horizon. The B horizon is in part a layer of transition from the overlying A to the underlying C horizon. The B horizon also has distinctive characteristics, such as (1) accumulation of clay, sesquioxides, humus, or a combination of these; (2) prismatic or blocky structure; (3) redder or browner colors than those in the A horizon; or (4) a combination of these.

C horizon.—The mineral horizon or layer, excluding indurated bedrock, that is little affected by soil-forming processes and does not have the properties typical of the overlying soil material. The material of a C horizon may be either like or unlike that in which the solum formed. If the material is known to differ from that in the solum, an Arabic numeral, commonly a 2, precedes the letter C.

Cr horizon.—Soft, consolidated bedrock beneath the soil.

R layer.—Consolidated bedrock beneath the soil. The bedrock commonly underlies a C horizon, but it can be directly below an A or a B horizon.

Humus. The well decomposed, more or less stable part of the organic matter in mineral soils.

Hydrologic soil groups. Refers to soils grouped according to their runoff potential. The soil properties that influence this potential are those that affect the minimum rate of water infiltration on a bare soil during periods after prolonged wetting when the soil is not frozen. These properties are depth to a seasonal high water table, the infiltration rate and permeability after prolonged wetting, and depth to a very slowly permeable layer. The slope and the kind of plant cover are not considered but are separate factors in predicting runoff.

Igneous rock. Rock formed by solidification from a molten or partially molten state. Major varieties include plutonic and volcanic rock. Examples are andesite, basalt, and granite.

Illuviation. The movement of soil material from one horizon to another in the soil profile. Generally, material is removed from an upper horizon and deposited in a lower horizon.

Impervious soil. A soil through which water, air, or roots penetrate slowly or not at all. No soil is absolutely impervious to air and water all the time.

Infiltration. The downward entry of water into the immediate surface of soil or other material, as contrasted with percolation, which is movement of water through soil layers or material.

Interfluve. An elevated area between two drainageways that sheds water to those drainageways.

Intermittent stream. A stream, or reach of a stream, that flows for prolonged periods only when it receives ground-water discharge or long, continued contributions from melting snow or other surface and shallow subsurface sources.

Iron depletions. Low-chroma zones having a low content of iron and manganese oxide because of chemical reduction and removal, but having a clay content similar to that of the adjacent matrix. A type of redoximorphic depletion.

Kame. An irregular, short ridge or hill of stratified glacial drift.

Knoll. A small, low, rounded hill rising above adjacent landforms.

K_{sat}. Saturated hydraulic conductivity. (See Permeability.)

Lacustrine deposit. Material deposited in lake water and exposed when the water level is lowered or the elevation of the land is raised.

Landform. Comprises a geomorphological unit, and is largely defined by its surface form and location in the landscape, as part of the terrain, and as such, is typically and element of topography.
Landslide. The rapid downhill movement of a mass of soil and loose rock, generally when wet or saturated. The speed and distance of movement, as well as the amount of soil and rock material, vary greatly.
Large stones (in tables). Rock fragments 3 inches (7.6 centimeters) or more across. Large stones adversely affect the specified use of the soil.
Leaching. The removal of soluble material from soil or other material by percolating water.
Lessivage. The translocation of clay colloids in a soil with no change in their chemical composition.
Linear extensibility. Refers to the change in length of an unconfined clod as moisture content is decreased from a moist to a dry state. Linear extensibility is used to determine the shrink-swell potential of soils. It is an expression of the volume change between the water content of the clod at $^1/_3$- or $^1/_{10}$-bar tension (33kPa or 10kPa tension) and oven dryness. Volume change is influenced by the amount and type of clay minerals in the soil. The volume change is the percent change for the whole soil. If it is expressed as a fraction, the resulting value is COLE, coefficient of linear extensibility.
Liquid limit. The moisture content at which the soil passes from a plastic to a liquid state.
Loam. Soil material that is 7 to 27 percent clay particles, 28 to 50 percent silt particles, and less than 52 percent sand particles.
Lodgment till. Compact glacial till deposited beneath the ice.
Loess. Fine grained material, dominantly of silt-sized particles, deposited by wind.
Low-residue crops. Such crops as corn used for silage, peas, beans, and potatoes. Residue from these crops is not adequate to control erosion until the next crop in the rotation is established. These crops return little organic matter to the soil.
Low strength. The soil is not strong enough to support loads.
Marine deposit. Material deposited in a sea or brackish-water environment, and exposed when the water level is lowered or the elevation of the land is raised.
Masses. Concentrations of substances in the soil matrix that do not have a clearly defined boundary with the surrounding soil material and cannot be removed as a discrete unit. Common compounds making up masses are calcium carbonate, gypsum or other soluble salts, iron oxide, and manganese oxide. Masses consisting of iron oxide or manganese oxide generally are considered a type of redoximorphic concentration.
Medium textured soil. Very fine sandy loam, loam, silt loam, or silt.
Metamorphic rock. Rock of any origin altered in mineralogical composition, chemical composition, or structure by heat, pressure, and movement. Nearly all such rocks are crystalline.
Mineral soil. Soil that is mainly mineral material and low in organic material. Its bulk density is more than that of organic soil.
Minimum tillage. Only the tillage essential to crop production and prevention of soil damage.
Miscellaneous area. An area that has little or no natural soil and supports little or no vegetation.
Moderately coarse textured soil. Coarse sandy loam, sandy loam, or fine sandy loam.
Moderately fine textured soil. Clay loam, sandy clay loam, or silty clay loam.
Mollic epipedon. A thick, dark, humus-rich surface horizon (or horizons) that has high base saturation and pedogenic soil structure. It may include the upper part of the subsoil.

Moraine. An accumulation of earth, stones, and other debris deposited by a glacier. Some types are terminal, lateral, medial, and ground.

Morphology, soil. The physical makeup of the soil, including the texture, structure, porosity, consistence, color, and other physical, mineral, and biological properties of the various horizons, and the thickness and arrangement of those horizons in the soil profile.

Mottling, soil. Irregular spots of different colors that vary in number and size. Descriptive terms are as follows: abundance—*few, common,* and *many;* size—*fine, medium,* and *coarse;* and contrast—*faint, distinct,* and *prominent*. The size measurements are of the diameter along the greatest dimension. *Fine* indicates less than 5 millimeters (about 0.2 inch); *medium,* from 5 to 15 millimeters (about 0.2 to 0.6 inch); and *coarse,* more than 15 millimeters (about 0.6 inch).

Mountain. A natural elevation of the land surface, rising more than 1,000 feet above surrounding lowlands, commonly of restricted summit area (relative to a plateau) and generally having steep sides. A mountain can occur as a single, isolated mass or in a group forming a chain or range.

Muck. Dark, finely divided, well decomposed organic soil material. (See Sapric soil material.)

Mudstone. Sedimentary rock formed by induration of silt and clay in approximately equal amounts.

Munsell notation. A designation of color by degrees of three simple variables—hue, value, and chroma. For example, a notation of 10YR 6/4 is a color with hue of 10YR, value of 6, and chroma of 4.

Narrowly defined map unit. Map unit boundaries were plotted and verified at closely spaced intervals. Maps were made at a scale of 1:24,000 or 2,000 feet to the inch, and the allowable minimum size of a soil delineation is 5 to 7 acres (Order 2 soil survey).

Neutral soil. A soil having a pH value of 6.6 to 7.3. (See Reaction, soil.)

Nodules. Cemented bodies lacking visible internal structure. Calcium carbonate, iron oxide, and manganese oxide are common compounds making up nodules. If formed in place, nodules of iron oxide or manganese oxide are considered types of redoximorphic concentrations.

Nose slope. A geomorphic component of hills consisting of the projecting end (laterally convex area) of a hillside. The overland water flow is predominantly divergent.

Nutrient, plant. Any element taken in by a plant essential to its growth. Plant nutrients are mainly nitrogen, phosphorus, potassium, calcium, magnesium, sulfur, iron, manganese, copper, boron, and zinc obtained from the soil and carbon, hydrogen, and oxygen obtained from the air and water.

Organic matter. Plant and animal residue in the soil in various stages of decomposition. The content of organic matter in the surface layer is described as follows:

Very low	less than 0.5 percent
Low	0.5 to 1.0 percent
Moderately low	1.0 to 2.0 percent
Moderate	2.0 to 4.0 percent
High	4.0 to 8.0 percent
Very high	more than 8.0 percent

Outwash plain. A landform of mainly sandy or coarse textured material of glaciofluvial origin. An outwash plain is commonly smooth; where pitted, it generally is low in relief.

Order 2 Soil Survey. Map unit boundaries were plotted and verified at closely spaced intervals. Maps were made at a scale of 1:24,000 or 2,000 feet to the inch, and the allowable minimum size of a soil delineation is 5 to 7 acres (Narrowly defined map unit).

Order 3 Soil Survey. Map unit boundaries were plotted and verified at wide intervals. Maps were made at a scale of 1:62.500 or 5,208 feet to the inch, and the allowable minimum size of a soil delineation is 40 acres (Broadly defined map unit).

Paleoterrace. An erosional remnant of a terrace that retains the surface form and alluvial deposits of its origin but was not emplaced by, and commonly does not grade to, a present-day stream or drainage network.

Pan. A compact, dense layer in a soil that impedes the movement of water and the growth of roots. For example, *hardpan, fragipan, claypan, plowpan,* and *traffic pan*.

Parent material. The unconsolidated organic and mineral material in which soil forms.

Peat. Unconsolidated material, largely undecomposed organic matter, that has accumulated under excess moisture. (See Fibric soil material.)

Ped. An individual natural soil aggregate, such as a granule, a prism, or a block.

Pedon. The smallest volume that can be called "a soil." A pedon is three dimensional and large enough to permit study of all horizons. Its area ranges from about 10 to 100 square feet (1 square meter to 10 square meters), depending on the variability of the soil.

Percolation. The movement of water through the soil.

Permeability. The quality of the soil that enables water or air to move downward through the profile. The rate at which a saturated soil transmits water is accepted as a measure of this quality. In soil physics, the rate is referred to as "saturated hydraulic conductivity," which is defined in the "Soil Survey Manual." In line with conventional usage in the engineering profession and with traditional usage in published soil surveys, this rate of flow continues to be expressed as "permeability." Terms describing permeability, measured in inches per hour, are as follows:

Impermeable	less than 0.0015 inch
Very slow	0.0015 to 0.06 inch
Slow	0.06 to 0.2 inch
Moderately slow	0.2 to 0.6 inch
Moderate	0.6 inch to 2.0 inches
Moderately rapid	2.0 to 6.0 inches
Rapid	6.0 to 20 inches
Very rapid	more than 20 inches

Phase, soil. A subdivision of a soil series based on features that affect its use and management, such as slope, stoniness, and flooding.

pH value. A numerical designation of acidity and alkalinity in soil. (See Reaction, soil.)

Piping (in tables). Formation of subsurface tunnels or pipelike cavities by water moving through the soil.

Pitting (in tables). Pits caused by melting around ice. They form on the soil after plant cover is removed.

Plasticity index. The numerical difference between the liquid limit and the plastic limit; the range of moisture content within which the soil remains plastic.

Plastic limit. The moisture content at which a soil changes from semisolid to plastic.

Plowpan. A compacted layer formed in the soil directly below the plowed layer.

Ponding. Standing water on soils in closed depressions. Unless the soils are artificially drained, the water can be removed only by percolation or evapotranspiration.

Poorly graded. Refers to a coarse grained soil or soil material consisting mainly of particles of nearly the same size. Because there is little difference in size of the particles, density can be increased only slightly by compaction.

Potential rooting depth (effective rooting depth). Depth to which roots could penetrate if the content of moisture in the soil were adequate. The soil has no properties restricting the penetration of roots to this depth.

Productivity, soil. The capability of a soil for producing a specified plant or sequence of plants under specific management.
Profile, soil. A vertical section of the soil extending through all its horizons and into the parent material.
Proper grazing use. Grazing at an intensity that maintains enough cover to protect the soil and maintain or improve the quantity and quality of the desirable vegetation. This practice increases the vigor and reproduction capacity of the key plants and promotes the accumulation of litter and mulch necessary to conserve soil and water.
Reaction, soil. A measure of acidity or alkalinity of a soil, expressed in pH values. A soil that tests to pH 7.0 is described as precisely neutral in reaction because it is neither acid nor alkaline. The degrees of acidity or alkalinity, expressed as pH values, are:

Ultra acid	less than 3.5
Extremely acid	3.5 to 4.4
Very strongly acid	4.5 to 5.0
Strongly acid	5.1 to 5.5
Moderately acid	5.6 to 6.0
Slightly acid	6.1 to 6.5
Neutral	6.6 to 7.3
Slightly alkaline	7.4 to 7.8
Moderately alkaline	7.9 to 8.4
Strongly alkaline	8.5 to 9.0
Very strongly alkaline	9.1 and higher

Redoximorphic concentrations. Nodules, concretions, soft masses, pore linings, and other features resulting from the accumulation of iron or manganese oxide. An indication of chemical reduction and oxidation resulting from saturation.
Redoximorphic depletions. Low-chroma zones from which iron and manganese oxide or a combination of iron and manganese oxide and clay has been removed. These zones are indications of the chemical reduction of iron resulting from saturation.
Redoximorphic features. Redoximorphic concentrations, redoximorphic depletions, reduced matrices, a positive reaction to alpha, alpha-dipyridyl, and other features indicating the chemical reduction and oxidation of iron and manganese compounds resulting from saturation.
Reduced matrix. A soil matrix that has low chroma in situ because of chemically reduced iron (Fe II). The chemical reduction results from nearly continuous wetness. The matrix undergoes a change in hue or chroma within 30 minutes after exposure to air as the iron is oxidized (Fe III). A type of redoximorphic feature.
Regolith. The unconsolidated mantle of weathered rock and soil material on the earth's surface; the loose earth material above the solid rock.
Relief. The elevations or inequalities of a land surface, considered collectively.
Residuum (residual soil material). Unconsolidated, weathered or partly weathered mineral material that accumulated as consolidated rock disintegrated in place.
Rill. A steep-sided channel resulting from accelerated erosion. A rill generally is a few inches deep and not wide enough to be an obstacle to farm machinery.
Road cut. A sloping surface produced by mechanical means during road construction. It is commonly on the uphill side of the road.
Rock fragments. Rock or mineral fragments having a diameter of 2 millimeters or more; for example, pebbles, cobbles, stones, and boulders.
Root zone. The part of the soil that can be penetrated by plant roots.
Runoff. The precipitation discharged into stream channels from an area. The water that flows off the surface of the land without sinking into the soil is called surface runoff. Water that enters the soil before reaching surface streams is called ground-water runoff or seepage flow from ground water.

Sand. As a soil separate, individual rock or mineral fragments from 0.05 millimeter to 2.0 millimeters in diameter. Most sand grains consist of quartz. As a soil textural class, a soil that is 85 percent or more sand and not more than 10 percent clay.

Sandstone. Sedimentary rock containing dominantly sand-sized particles.

Sapric soil material (muck). The most highly decomposed of all organic soil material. Muck has the least amount of plant fiber, the highest bulk density, and the lowest water content at saturation of all organic soil material.

Saprolite. Unconsolidated residual material underlying the soil and grading to hard bedrock below.

Saturation. Wetness characterized by zero or positive pressure of the soil water. Under conditions of saturation, the water will flow from the soil matrix into an unlined auger hole.

Scarification. The act of abrading, scratching, loosening, crushing, or modifying the surface to increase water absorption or to provide a more tillable soil.

Sedimentary rock. Rock made up of particles deposited from suspension in water. The chief kinds of sedimentary rock are conglomerate, formed from gravel; sandstone, formed from sand; shale, formed from clay; and limestone, formed from soft masses of calcium carbonate. There are many intermediate types. Some wind-deposited sand is consolidated into sandstone.

Sequum. A sequence consisting of an illuvial horizon and the overlying eluvial horizon. (See Eluviation.)

Series, soil. A group of soils that have profiles that are almost alike, except for differences in texture of the surface layer. All the soils of a series have horizons that are similar in composition, thickness, and arrangement.

Sheet erosion. The removal of a fairly uniform layer of soil material from the land surface by the action of rainfall and surface runoff.

Shoulder. The position that forms the uppermost inclined surface near the top of a hillslope. It is a transition from backslope to summit. The surface is dominantly convex in profile and erosional in origin.

Shrink-swell (in tables). The shrinking of soil when dry and the swelling when wet. Shrinking and swelling can damage roads, dams, building foundations, and other structures. It can also damage plant roots.

Side slope. A geomorphic component of hills consisting of a laterally planar area of a hillside. The overland waterflow is predominantly parallel.

Silica. A combination of silicon and oxygen. The mineral form is called quartz.

Silt. As a soil separate, individual mineral particles that range in diameter from the upper limit of clay (0.002 millimeter) to the lower limit of very fine sand (0.05 millimeter). As a soil textural class, soil that is 80 percent or more silt and less than 12 percent clay.

Similar soils. Soils that share limits of diagnostic criteria, behave and perform in a similar manner, and have similar conservation needs or management requirements for the major land uses in the survey area.

Sinkhole. A depression in the landscape where limestone has been dissolved.

Site index. A designation of the quality of a forest site based on the height of the dominant stand at an arbitrarily chosen age. For example, if the average height attained by dominant and codominant trees in a fully stocked stand at the age of 50 years is 75 feet, the site index is 75.

Slickensides. Polished and grooved surfaces produced by one mass sliding past another. In soils, slickensides may occur at the bases of slip surfaces on the steeper slopes; on faces of blocks, prisms, and columns; and in swelling clayey soils, where there is marked change in moisture content.

Slope. The inclination of the land surface from the horizontal. Percentage of slope is the vertical distance divided by horizontal distance, then multiplied by 100. Thus, a slope of 20 percent is a drop of 20 feet in 100 feet of horizontal distance. In this survey, classes for simple slopes are as follows:

Nearly level	0 to 3 percent
Gently sloping	3 to 8 percent
Strongly sloping	8 to 15 percent
Moderately steep	15 to 25 percent
Steep	25 to 35 percent
Very steep	35 percent and higher

Slow refill (in tables). The slow filling of ponds, resulting from restricted permeability in the soil.

Sodium adsorption ratio (SAR). A measure of the amount of sodium (Na) relative to calcium (Ca) and magnesium (Mg) in the water extract from saturated soil paste. It is the ratio of the Na concentration divided by the square root of one-half of the Ca + Mg concentration.

Soft bedrock. Bedrock that can be excavated with trenching machines, backhoes, small rippers, and other equipment commonly used in construction.

Soil. A natural, three-dimensional body at the earth's surface. It is capable of supporting plants and has properties resulting from the integrated effect of climate and living matter acting on earthy parent material, as conditioned by relief over periods of time.

Soil separates. Mineral particles less than 2 millimeters in equivalent diameter and ranging between specified size limits. The names and sizes, in millimeters, of separates recognized in the United States are as follows:

Very coarse sand	2.0 to 1.0
Coarse sand	1.0 to 0.5
Medium sand	0.5 to 0.25
Fine sand	0.25 to 0.10
Very fine sand	0.10 to 0.05
Silt	0.05 to 0.002
Clay	less than 0.002

Solum. The upper part of a soil profile, above the C horizon, in which the processes of soil formation are active. The solum in soil consists of the A, E, and B horizons. Generally, the characteristics of the material in these horizons are unlike those of the material below the solum. The living roots and plant and animal activities are largely confined to the solum.

Spodic horizon. A dark reddish brown or reddish brown soil layer with fine sandy loam or coarser texture. This layer is a result of illuviated organic matter and aluminum, with or without iron.

Stone line. A concentration of coarse fragments in a soil. Generally, it is indicative of an old weathered surface. In a cross section, the line may be one fragment or more thick. It generally overlies material that weathered in place and is overlain by recent sediment of variable thickness.

Stones. Rock fragments 10 to 24 inches (25 to 60 centimeters) in diameter if rounded or 15 to 24 inches (38 to 60 centimeters) in length if flat.

Stony. Refers to a soil containing stones in numbers that interfere with or prevent tillage.

Stripcropping. Growing crops in a systematic arrangement of strips or bands that provide vegetative barriers to wind erosion and water erosion.

Structure, soil. The arrangement of primary soil particles into compound particles or aggregates. The principal forms of soil structure are—*platy* (laminated), *prismatic* (vertical axis of aggregates longer than horizontal), *columnar* (prisms with rounded tops), *blocky* (angular or subangular), and *granular*. *Structureless* soils are either *single grained* (each grain by itself, as in dune sand) or *massive* (the particles adhering without any regular cleavage, as in many hardpans).

Stubble mulch. Stubble or other crop residue left on the soil or partly worked into the soil. It protects the soil from wind erosion and water erosion after harvest, during preparation of a seedbed for the next crop, and during the early growing period of the new crop.

Subsoil. Technically, the B horizon; roughly, the part of the solum below plow depth.

Subsoiling. Tilling a soil below normal plow depth, ordinarily to shatter a hardpan or claypan.

Substratum. The part of the soil below the solum.

Subsurface layer. Any surface soil horizon (A, E, AB, or EB) below the surface layer.

Summit. The topographically highest position of a hillslope. It has a nearly level (planar or only slightly convex) surface.

Surface layer. The soil ordinarily moved in tillage, or its equivalent in uncultivated soil, ranging in depth from 4 to 10 inches (10 to 25 centimeters). Frequently designated as the "plow layer," or the "Ap horizon."

Surface soil. The A, E, AB, and EB horizons, considered collectively. It includes all subdivisions of these horizons.

Talus. Fragments of rock and other soil material accumulated by gravity at the foot of cliffs or steep slopes.

Taxadjuncts. Soils that cannot be classified in a series recognized in the classification system. Such soils are named for a series they strongly resemble and are designated as taxadjuncts to that series because they differ in ways too small to be of consequence in interpreting their use and behavior. Soils are recognized as taxadjuncts only when one or more of their characteristics are slightly outside the range defined for the family of the series for which the soils are named.

Terminal moraine. A belt of thick glacial drift that generally marks the termination of important glacial advances.

Terrace. An embankment, or ridge, constructed across sloping soils on the contour or at a slight angle to the contour. The terrace intercepts surface runoff so that water soaks into the soil or flows slowly to a prepared outlet. A terrace in a field generally is built so that the field can be farmed. A terrace intended mainly for drainage has a deep channel that is maintained in permanent sod.

Terrace (geologic). An old alluvial plain, ordinarily flat or undulating, bordering a river, a lake, or the sea.

Texture, soil. The relative proportions of sand, silt, and clay particles in a mass of soil. The basic textural classes, in order of increasing proportion of fine particles, are *sand, loamy sand, sandy loam, loam, silt loam, silt, sandy clay loam, clay loam, silty clay loam, sandy clay, silty clay,* and *clay*. The sand, loamy sand, and sandy loam classes may be further divided by specifying "coarse," "fine," or "very fine."

Thin layer (in tables). Otherwise suitable soil material that is too thin for the specified use.

Till plain. An extensive area of nearly level to undulating soils underlain by glacial till.

Tilth, soil. The physical condition of the soil as related to tillage, seedbed preparation, seedling emergence, and root penetration.

Toeslope. The position that forms the gently inclined surface at the base of a hillslope. Toeslopes in profile are commonly gentle and linear and are constructional surfaces forming the lower part of a hillslope continuum that grades to valley or closed-depression floors.

Topsoil. The upper part of the soil, which is the most favorable material for plant growth. It is ordinarily rich in organic matter and is used to topdress roadbanks, lawns, and land affected by mining.

Trace elements. Chemical elements, for example, zinc, cobalt, manganese, copper, and iron, in soils in extremely small amounts. They are essential to plant growth.

Upland. Land at a higher elevation, in general, than the alluvial plain or stream terrace; land above the lowlands along streams.

Variegation. Refers to patterns of contrasting colors assumed to be inherited from the parent material rather than to be the result of poor drainage.

Varve. A sedimentary layer or a lamina or sequence of laminae deposited in a body of still water within a year. Specifically, a thin pair of graded glaciolacustrine layers seasonally deposited, usually by meltwater streams, in a glacial lake or other body of still water in front of a glacier.

Water bars. Smooth, shallow ditches or depressional areas that are excavated at an angle across a sloping road. They are used to reduce the downward velocity of water and divert it off and away from the road surface. Water bars can easily be driven over if constructed properly.

Water-worked (wave-worked) deposits. Material remaining from an ancient shoreline of a lake or sea. Much of the clay and silt particles have been washed out by wave movement leaving behind mostly sand, gravel or cobbles.

Weathering. All physical and chemical changes produced in rocks or other deposits at or near the earth's surface by atmospheric agents. These changes result in disintegration and decomposition of the material.

Well graded. Refers to soil material consisting of coarse grained particles that are well distributed over a wide range in size or diameter. Such soil normally can be easily increased in density and bearing properties by compaction. Contrasts with poorly graded soil.

Wilting point (or permanent wilting point). The moisture content of soil, on an ovendry basis, at which a plant (specifically a sunflower) wilts so much that it does not recover when placed in a humid, dark chamber.

Windthrow. The uprooting and tipping over of trees by the wind.

Average # of days per year with at least 1 inch of snow on the ground: 139

*A growing degree day is a unit of heat available for plant growth. It can be calculated by adding the maximum and minimum daily temperatures, dividing the sum by 2, and subtracting the temperature below which growth is minimal for the principal crops in the area (Threshold: 40.0 deg. F).

Table 1.—Temperature and Precipitation—Continued

Table 8.—Hazard of Erosion and Soil Rutting on Forestland

[The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.01 to 1.00. The larger the value, the greater the limitation. See text for further explanation of ratings in this table.]

* Depths and duration (months) of seasonal saturation can be found in the Water Table section of the 'Water Features' table.

				Low strength	1.00

* Depths and duration (months) of seasonal saturation can be found in the Water Table section of the 'Water Features' table.

Table 9.—Haul Roads, Log Landings, and Harvest Equipment Operation on Forestland

[The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.01 to 1.00. The larger the value, the greater the limitation. See text for further explanation of ratings in this table.]

* Depths and duration (months) of seasonal saturation can be found in the Water Table section of the 'Water Features' table.

Table 10.—Seedling Mortality and Windthrow Hazard on Forestland

[The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.01 to 1.00. The larger the value, the greater the limitation. See text for further explanation of ratings in this table.]

Table 16.—Construction Materials

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The ratings given for the thickest layer are for the thickest layer above any restriction and excluding the bottom layer. The numbers in the value columns range from 0.00 to 0.99. The greater the value, the greater the likelihood that the bottom layer or thickest layer of the soil is a source of sand or gravel. See text for further explanation of ratings in this table.)

Map symbol and soil name	Pct. of map unit	Potential source of gravel: Rating class	Value	Potential source of sand: Rating class	Value
10A:					
Pleasant Lake-------	45	Improbable		Improbable	
		Bottom layer	0.00	Bottom layer	0.00

Table 17.—Source of Reclamation Material, Roadfill, and Topsoil

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.00 to 0.99. The smaller the value, the greater the limitation. See text for further explanation of ratings in this table.)

	Organic Soils				
Low lime, shallow or very shallow to meta-igneous bedrock, 500 to 3,000 feet in elevation**	Knob Lock				
Low lime, shallow or very shallow to meta-igneous bedrock, > 3,000 feet in elevation***	Ricker				
Medium to high lime, mucky, very deep to mineral, < 500 feet in elevation*					Catden
Medium to high lime, mucky over Whallonsburg clayey, < 500 feet in elevation*					
Medium to high lime, mucky, very deep to mineral, 500 to 3,000 feet in elevation**					Bucksport

See footnotes at end of table.

Table 25.—Relationship between Soil Series, their Parent Material, Landscape Position, and Drainage—Continued

Nature of Parent Material	Excessively drained to well drained	Moderately well drained	Somewhat poorly drained	Poorly drained	Very poorly drained
	Organic Soils				
Medium to high lime, mucky over loamy, 500 to 3,000 feet in elevation**					Wonsqueak
Low lime, mucky, very deep to mineral, 500 to 3,000 feet in elevation**					Pleasant Lake
Low lime, mucky over sandy, 500 to 3,000 feet in elevation**					Burnt Vly
Low lime, undifferentiated muck, 500 to 3,000 feet in elevation**					Haplosaprists
	Miscellaneous Soil Types				
	Udorthents				
	Udorthents, mine spoil				
	Pits, quarry				
	Pits, sand and gravel				

* This zone represents the mesic soil temperature area.
** This zone represents part or all of the frigid soil temperature area.
*** This zone represents the cryic soil temperature area.

Table 26.—Taxonomic Classification of the Soils

(An asterisk in the first column indicates a taxadjunct to the series. See text for a description of those characteristics that are outside the range of the series.)

Soil name	Family or higher taxonomic class
Adams	Sandy, isotic, frigid Typic Haplorthods
Adirondack	Coarse-loamy, isotic, frigid Typic Endoaquods
Amenia	Coarse-loamy, mixed, active, mesic Aquic Eutrudepts
Ampersand	Coarse-loamy, isotic, frigid Typic Epiaquods
Andic Cryaquods	Andic Cryaquods
Becket	Coarse-loamy, isotic, frigid Oxyaquic Haplorthods
Bombay	Coarse-loamy, mixed, active, mesic Oxyaquic Hapludalfs
Bucksport	Euic, frigid Typic Haplosaprists
Burnt Vly	Sandy or sandy-skeletal, mixed, dysic, frigid Terric Haplosaprists
Catden	Euic, mesic Typic Haplosaprists
Cayuga	Fine, illitic, mesic Oxyaquic Glossudalfs
Champlain	Mixed, frigid Typic Udipsamments
Charles	Coarse-silty, mixed, superactive, nonacid, frigid Aeric Fluvaquents
Charlton	Coarse-loamy, mixed, active, mesic Typic Dystrudepts
Chatfield	Coarse-loamy, mixed, superactive, mesic Typic Dystrudepts
Churchville	Fine, illitic, mesic Aeric Endoaqualfs
Claverack	Sandy over clayey, mixed, superactive, nonacid, mesic Aquic Udorthents
Collamer	Fine-silty, mixed, active, mesic Glossaquic Hapludalfs
Colonie	Mixed, mesic Lamellic Udipsamments
Colton	Sandy-skeletal, isotic, frigid Typic Haplorthods
Cornish	Coarse-silty, mixed, superactive, frigid Fluvaquentic Dystrudepts
*Cosad	Sandy over clayey, mixed, superactive, mesic Aquic Eutrudepts
Couchsachraga	Sandy, isotic Lithic Humicryods
Covington	Very-fine, mixed, active, mesic Mollic Endoaqualfs
Croghan	Sandy, isotic, frigid Aquic Haplorthods
Deerfield	Mixed, mesic Aquic Udipsamments
Depeyster	Fine-silty, mixed, active, frigid Aquic Glossudalfs
Dunkirk	Fine-silty, mixed, active, mesic Glossic Hapludalfs
Duxbury	Sandy, isotic, frigid Typic Haplorthods
Elmridge	Coarse-loamy over clayey, mixed, semiactive, mesic Aquic Dystric Eutrudepts
Esther	Medial, amorphic Aquandic Humicryods
Factoryville	Mixed, mesic Oxyaquic Udipsamments
Farmington	Loamy, mixed, active, mesic Lithic Eutrudepts
Fernlake	Sandy, isotic, frigid Entic Haplorthods
Fluvaquents	Fluvaquents
Galway	Coarse-loamy, mixed, superactive, mesic Typic Eutrudepts
Georgia	Coarse-loamy, mixed, semiactive, mesic Aquic Dystric Eutrudepts
Gougeville	Mixed, mesic Humaqueptic Psammaquents
Hailesboro	Fine-silty, mixed, superactive, frigid Aeric Endoaqualfs
Haplosaprists	Haplosaprists
Hartland	Coarse-silty, mixed, active, mesic Dystric Eutrudepts
Hermon	Sandy-skeletal, isotic, frigid Typic Haplorthods
Hogback	Loamy, isotic, frigid Lithic Haplohumods
Hollis	Loamy, mixed, active, mesic Lithic Dystrudepts
Howard	Loamy-skeletal, mixed, active, mesic Glossic Hapludalfs
Kalurah	Coarse-loamy, mixed, semiactive, frigid Aquic Dystric Eutrudepts
Kingsbury	Very-fine, mixed, active, mesic Aeric Endoaqualfs
Knob Lock	Dysic, frigid Lithic Udifolists
Livingston	Very-fine, mixed, active, nonacid, mesic Mollic Endoaquepts
Lovewell	Coarse-silty, mixed, superactive, frigid Fluvaquentic Dystrudepts
Lyman	Loamy, isotic, frigid Lithic Haplorthods
Malone	Coarse-loamy, mixed, active, nonacid, frigid Aeric Epiaquepts
Massena	Coarse-loamy, mixed, active, nonacid, mesic Aeric Endoaquepts
*Medomak	Coarse-silty, mixed, superactive, frigid Fluvaquentic Endoaquolls
Monadnock	Coarse-loamy over sandy or sandy-skeletal, isotic, frigid Typic Haplorthods
Mooers	Mixed, frigid Oxyaquic Udipsamments
Mundalite	Coarse-loamy, isotic, frigid Oxyaquic Haplorthods
Naumburg	Sandy, isotic, frigid Typic Endoaquods
Nehasne	Coarse-loamy, mixed, active, frigid Dystric Eutrudepts
Nellis	Coarse-loamy, mixed, superactive, mesic Typic Eutrudepts
Niagara	Fine-silty, mixed, active, mesic Aeric Endoaqualfs
Nicholville	Coarse-silty, isotic, frigid Aquic Haplorthods

Table 26.—Taxonomic Classification of the Soils—Continued

Soil name	Family or higher taxonomic class
Occum	Coarse-loamy, mixed, superactive, mesic Fluventic Dystrudepts
Ondawa	Coarse-loamy, mixed, active, frigid Fluventic Dystrudepts
Pittsfield	Coarse-loamy, mixed, active, mesic Dystric Eutrudepts
Pleasant Lake	Dysic, frigid Typic Haplosaprists
Podunk	Coarse-loamy, mixed, active, frigid Fluvaquentic Dystrudepts
Pootatuck	Coarse-loamy, mixed, active, mesic Fluvaquentic Dystrudepts
Pyrities	Coarse-loamy, mixed, active, frigid Dystric Eutrudepts
Rawsonville	Coarse-loamy, isotic, frigid Typic Haplohumods
Ricker	Dysic Lithic Cryofolists
*Rippowam	Coarse-loamy, mixed, superactive, nonacid, mesic Aeric Fluvaquents
Roundabout	Coarse-silty, mixed, active, nonacid, frigid Aeric Epiaquepts
Rumney	Coarse-loamy, mixed, active, nonacid, frigid Fluvaquentic Endoaquepts
Santanoni	Sandy-skeletal, isotic Typic Humicryods
Searsport	Sandy, mixed, frigid Histic Humaquepts
Skerry	Coarse-loamy, isotic, frigid Aquic Haplorthods
Skylight	Sandy, isotic Lithic Humicryods
Stafford	Mixed, mesic Typic Psammaquents
Sun	Coarse-loamy, mixed, active, nonacid, mesic Aeric Epiaquepts
Sunapee	Coarse-loamy, isotic, frigid Aquic Haplorthods
Tahawus	Sandy, mixed, frigid Histic Humaquepts
Tonawanda	Coarse-silty, mixed, active, nonacid, mesic Aeric Endoaquepts
Tunbridge	Coarse-loamy, isotic, frigid Typic Haplorthods
Typic Endoaquolls	Typic Endoaquolls
Udifluvents	Udifluvents
Udorthents	Udorthents
Udorthents, mine spoil	Udorthents
Vergennes	Very-fine, mixed, active, mesic Glossaquic Hapludalfs
Wallface	Medial, amorphic Andic Humicryods
Wegatchie	Fine-silty, mixed, active, nonacid, frigid Mollic Endoaquepts
Whallonsburg	Clayey, mixed, euic, mesic Terric Haplosaprists
Wilmington	Loamy, isotic, frigid, shallow Typic Endoaquods
Windsor	Mixed, mesic Typic Udipsamments
Wonsqueak	Loamy, mixed, euic, frigid Terric Haplosaprists

NRCS Accessibility Statement

The Natural Resources Conservation Service (NRCS) is committed to making its information accessible to all of its customers and employees. If you are experiencing accessibility issues and need assistance, please contact our Helpdesk by phone at 1-800-457-3642 or by e-mail at ServiceDesk-FTC@ftc.usda.gov. For assistance with publications that include maps, graphs, or similar forms of information, you may also wish to contact our State or local office. You can locate the correct office and phone number at http://offices.sc.egov.usda.gov/locator/app.

FEATURE AND SYMBOL LEGEND FOR SOIL SURVEY

CULTURAL FEATURES

BOUNDARIES

- National, state, or province
- County or parish
- Minor civil division
- Limit of soil survey (label) and/or denied access area
- Field sheet matchline and neatline

HYDROGRAPHIC FEATURES

STREAMS

Perennial stream, double line	
Perennial stream, single line	Label only
Intermittent stream	Label only
Drainage end	Label only
Spring	

SOIL SURVEY FEATURES

SOIL DELINEATIONS AND SYMBOLS 10A 13A

LANDFORM FEATURES

- Bedrock escarpment
- Other than bedrock escarpment
- Short steep slope
- Gully

MISCELLANEOUS SURFACE FEATURES

- Clay spot
- Gravel pit
- Gravelly spot
- Marsh or swamp
- Mine or quarry
- Rock outcrop
- Sandy spot
- Stony spot
- Very stony spot
- Wet spot

Joins sheet 9 Port Douglas

Joins sheet 8 Clintonville

Joins sheet 10 Juniper Island

This soil survey was compiled by the U.S. Department of Agriculture, Natural Resources Conservation Service and cooperating agencies. Base maps are orthophotographs prepared by the U.S. Department of the Interior, Geological Survey, from 1994-1999 aerial photography. Administrative boundaries were acquired from the State of New York. Boundaries may have been edited to conform with features represented on the publication orthophotography or to enhance the clarity of the soils information.

North American Datum of 1983(NAD83). GRS80 Spheroid 1000-meter ticks: Universal Transverse Mercator, zone 18. Coordinate grid ticks and land division data, if shown, are approximately positioned. Digital data are available for this quadrangle.

ESSEX COUNTY, NEW YORK
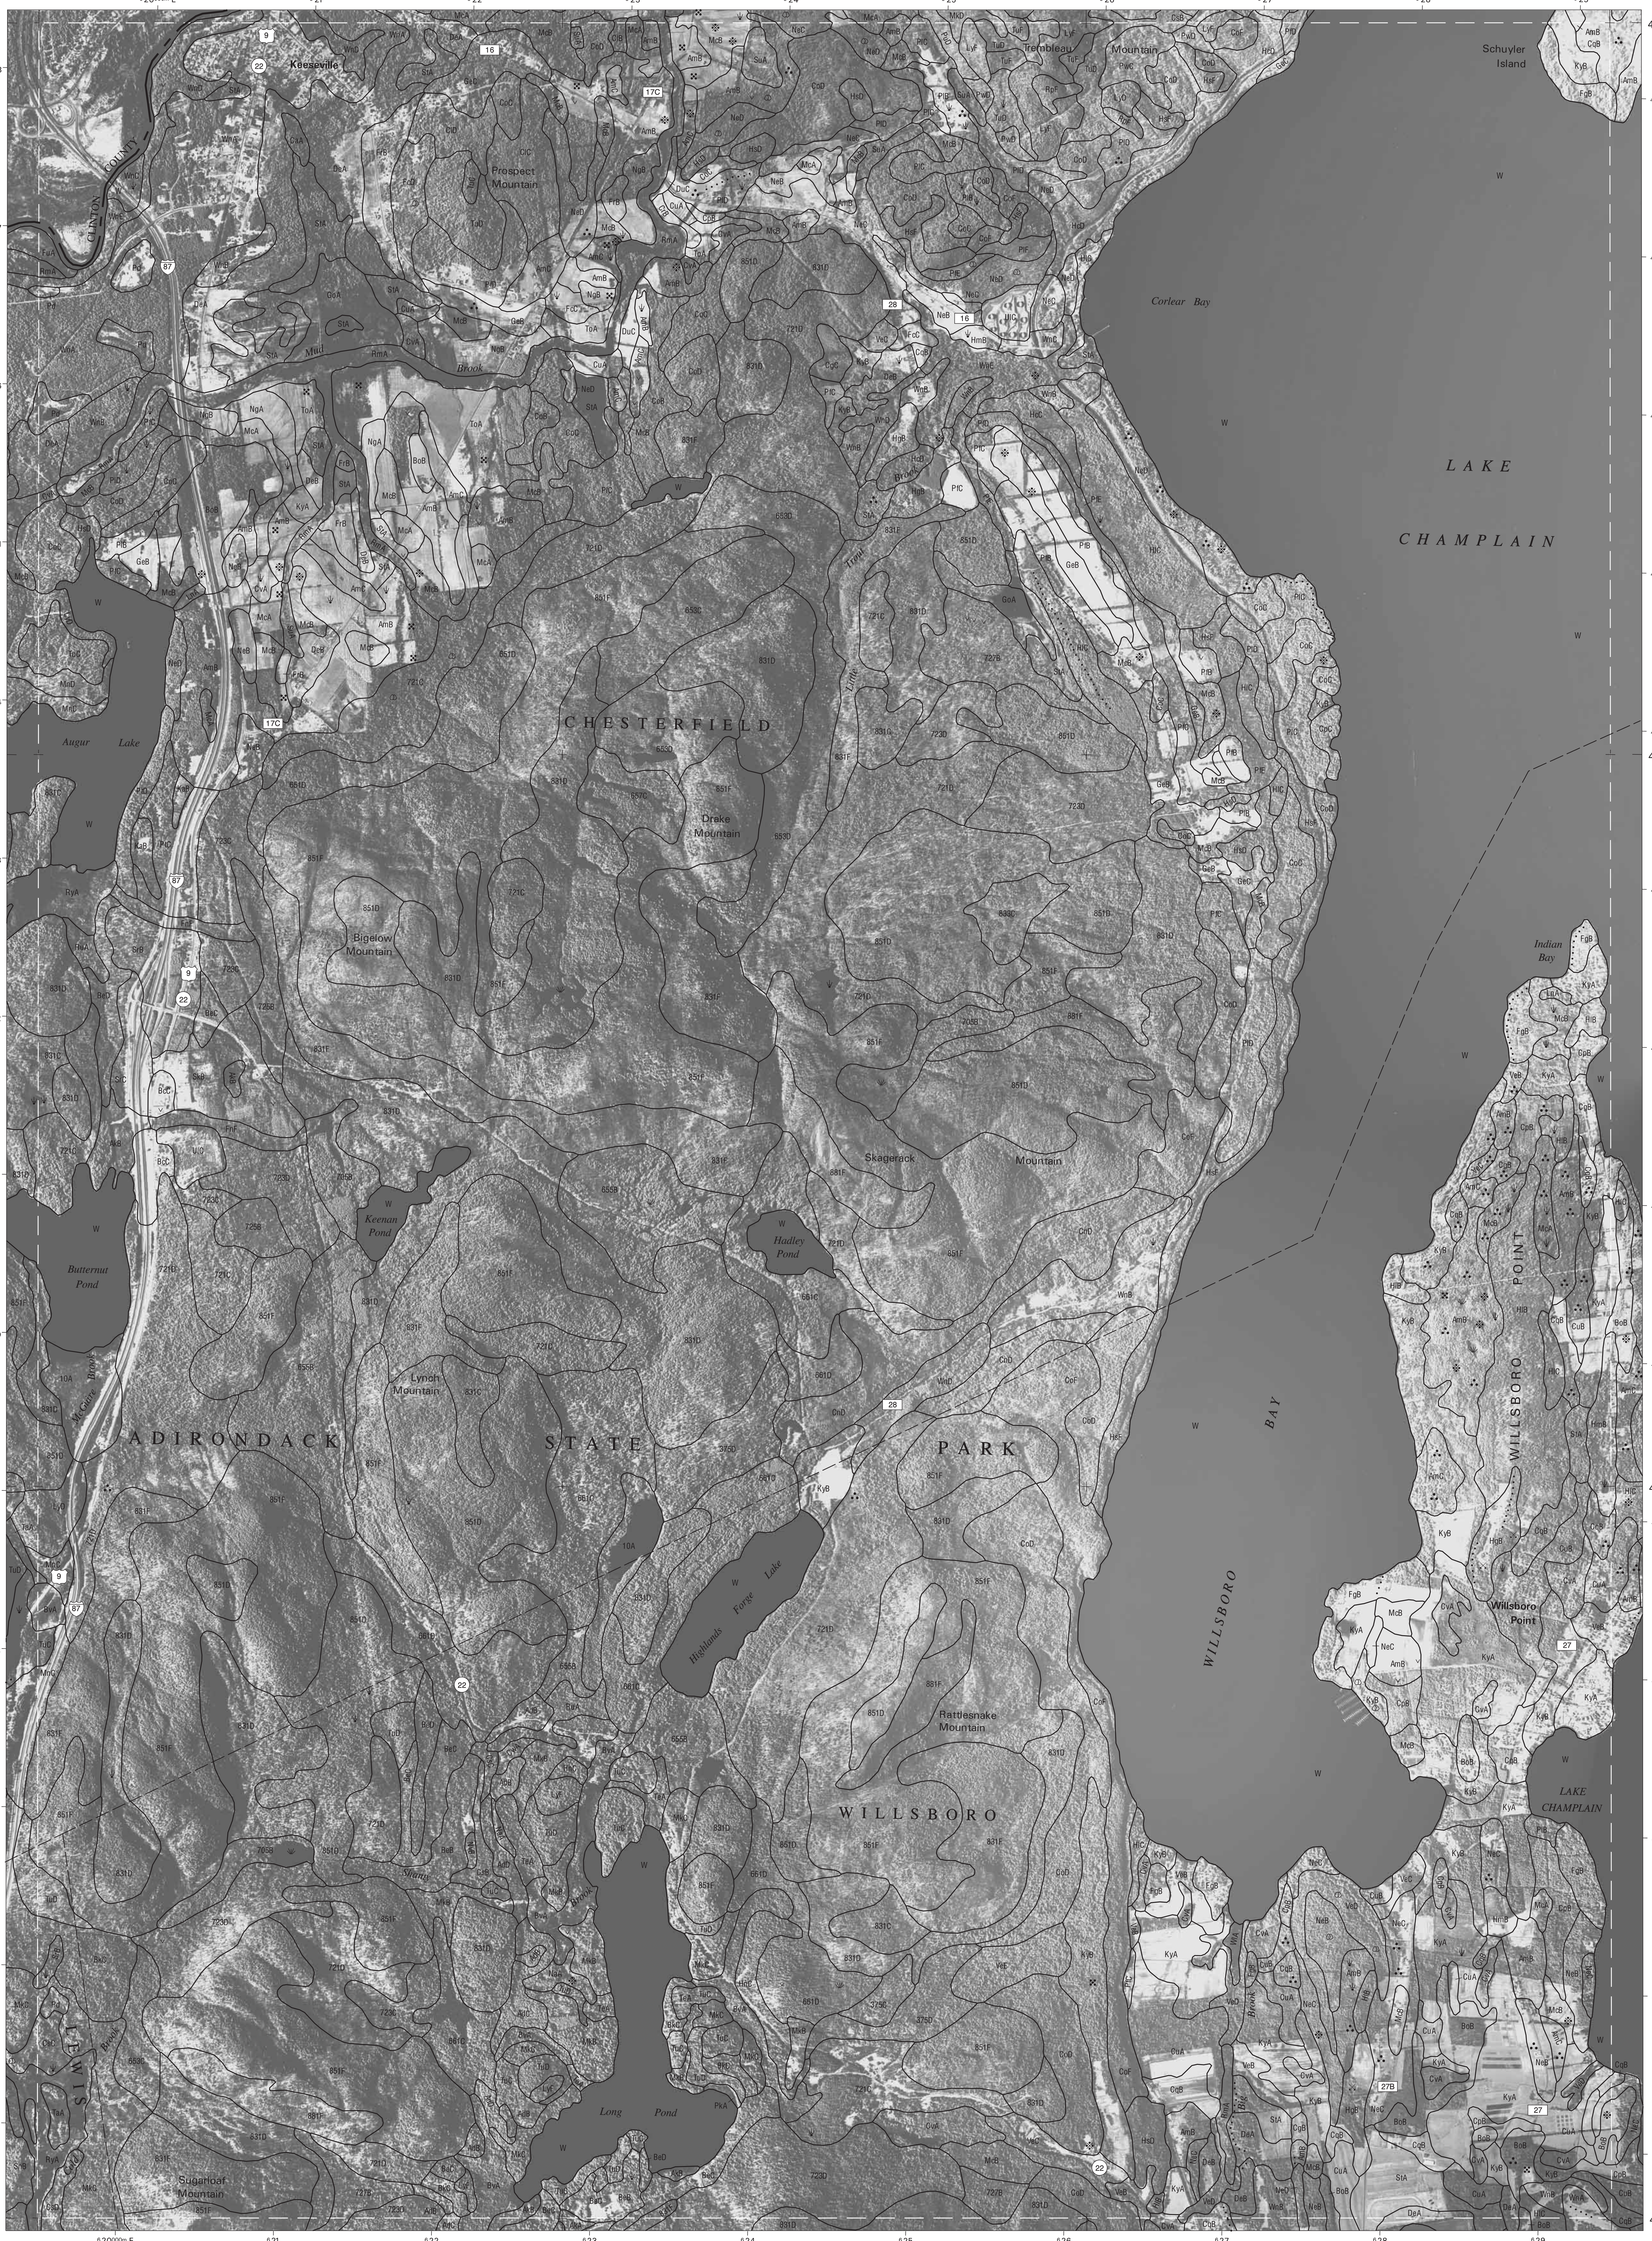
PORT DOUGLAS QUADRANGLE
SHEET NUMBER 9 OF 51



This soil survey was compiled by the U.S. Department of Agriculture, Natural Resources Conservation Service and cooperating agencies. Base maps are orthophotographs prepared by the U.S. Department of the Interior, Geological Survey, from 1994-1999 aerial photography. Administrative boundaries were acquired from the State of New York. Boundaries may have been edited to conform with features represented on the publication orthophotography or to enhance the clarity of the soils information.

North American Datum of 1983(NAD83). GRS80 Spheroid 1000-meter ticks: Universal Transverse Mercator, zone 18. Coordinate grid ticks and land division data, if shown, are approximately positioned. Digital data are available for this quadrangle.
